

Assessment Title
Multi-Cloud Security Integration and Project Management

CCC604 | Assessment-7

The Student Name | Geni Bahar
Student ID | 270850228

Group | Student_Group_01-FT
Team Members | Yusof Sharifzai (270707435), Hari Tamang (270860695)

Tutor/Assessor | Ovesh Vohra, Riddhi Joshi

Programme
Diploma in Cloud Computing and Cyber Security (120 Credits)

Course
CCC 604: Multi-Cloud Security Integration and Project Management
(Level 6, 30 Credits)

Date: 28th June 2026

Task 1: Project Planning, Design, and Assignment of Group and Individual Roles

Introduction to the Project and Group

Secure Multi-Cloud Migration of Yoobee College WordPress Infrastructure (AWS + Azure + Fortinet)

In this project, our group planned and built a multi-cloud setup for Yoobee College's WordPress-based infrastructure. The main workload was hosted in AWS, while Azure was used for identity, DNS, RBAC, MFA and access testing. Fortinet FortiGate was added as the main security component for firewall control, VPN connectivity and traffic inspection.

The focus was not just to create resources, but to show how the setup can be managed securely. In AWS we used services such as VPC, EC2, RDS, ELB, Auto Scaling, S3, Lambda, CloudWatch, SNS, IAM and ACM. In Azure we used the subscription, RBAC, Azure AD tenant, MFA and Azure DNS.

FortiGate was included to show how inter-cloud traffic can be controlled instead of leaving the two cloud environments separate.

We believe this design fits the assessment because it brings together the main areas we worked on in the course: cloud networking, identity, DNS, monitoring, backup and security. It also showed us that making AWS, Azure and FortiGate work together is not always straightforward.

Group Members:

Name	Student ID	Role Summary
Yusof Sharifzai	270707435	Cloud Engineer - Azure and Co-Project Manager. Responsible for Azure subscription validation, Azure RBAC with MFA, Azure AD tenant configuration, Azure DNS setup, and VPN/HTTPS testing evidence.
Geni Bahar	270850228	Security Architect - AWS and Co-Project Manager. Responsible for AWS VPC, EC2, RDS, S3, Lambda, ELB, Auto Scaling, SNS, CloudWatch, OpenVPN, IAM, ACM, and Fortinet integration evidence.
Hari Tamang	270860695	Project Coordinator and Testing Support. Responsible for project scheduling, milestone tracking, screenshot collection, test verification support, and assisting with AWS/Azure/Fortinet configuration evidence.

Individual Student Responsibilities

Name	Role	Responsibilities
Yusof Sharifzai	Cloud Engineer (Azure) & Co-Project Manager	Create and validate the Azure subscription; configure Azure RBAC and MFA; create the Azure AD tenant using the group name; configure Azure DNS; link Azure DNS records to the AWS load balancer/DNS endpoint; test HTTPS access through Azure DNS; document Azure screenshots and support the final report.
Geni Bahar	AWS Security Architect and Co-Project Manager	Design and deploy the AWS VPC with public/private subnets, Internet Gateway, NAT Gateway, route tables, and security controls; configure EC2 WordPress hosting, RDS MySQL, IAM roles, S3, Lambda snapshot automation, CloudWatch monitoring, SNS notifications, ACM HTTPS, ELB/Auto Scaling, OpenVPN private access, and Fortinet security integration. Also responsible for AWS evidence, technical explanation, and security design alignment.
Hari Tamang	Project Coordinator and Testing Support Engineer	Maintain the project schedule and milestone tracking; support testing for HTTPS, VPN, load balancing, monitoring, and backup validation; assist with screenshot collection; support Fortinet/VPN evidence collection; help review final documentation for completeness, formatting, and submission readiness.

Project Layout and Diagram (Geni)

Figure 1 shows the final high-level design we followed for the project. The diagram helped us separate the main parts of the environment, such as public access, application hosting, database, VPN, monitoring and backup. AWS hosts the WordPress workload, Azure supports identity/DNS/testing, and FortiGate sits as the security control point between the cloud environments.

Step-by-step Checklist for Timely Completion (Yusof)

Phase 1: Project Planning - Yusof Leads, Geni Supports (11-18 May 2026)

- Finalise group roles (Yusof = Azure, Geni = AWS, Hari = Project coordination)
- Define project scope and objectives
- Create architecture diagram (with Fortinet placement)
- Complete Task 1 planning document

Phase 2: AWS Implementation - Geni Leads (18-31 May 2026)

- Create VPC with public/private subnets, IGW, NAT Gateway, route tables
- Launch EC2 Amazon Linux instance
- Configure Security Groups with required ports
- Create IAM roles (EC2 + S3 access, Lambda function role)
- Deploy RDS MySQL as backend database
- Configure Application Load Balancer + ACM SSL/TLS certificate
- Set up Auto Scaling group
- Create Lambda function for daily EC2 snapshot
- Set up S3 bucket for snapshot backups
- Configure CloudWatch to monitor EC2 start/stop events
- Set up SNS topic with Yoobee student email notification
- Deploy OpenVPN for private IP access

Phase 3: Azure Implementation - Yusof Leads (1-7 June 2026)

- Create Microsoft Azure subscription
- Verify subscription balance and validity
- Configure RBAC with MFA on the account
- Create Azure AD tenant with our group name
- Configure Azure DNS zone
- Register or update DNS name server records and validate DNS propagation
- Configure Azure DNS records to point to the AWS load balancer endpoint and verify HTTPS access
- Test VPN client access to WordPress site via HTTPS

Phase 4: Fortinet Integration - Geni Leads, Yusof Supports (8-14 June 2026)

- Deploy FortiGate (AWS Marketplace)
- Configure VPN tunnels between AWS ↔ FortiGate ↔ Azure
- Define firewall rules and inspection policies
- Document inter-cloud traffic security controls
- Update architecture diagram with Fortinet placement

Phase 5: Risk Assessment & Incident Analysis - All Members (8-14 June 2026)

- Complete risk assessment table (minimum 5 risks with mitigations)
- Document the security issue identified during testing with detection and response timeline
- Document detection, response, and recovery plan
- Include CloudWatch, CloudTrail, Azure Monitor logs

Phase 6: Testing & Verification - All Members (15-21 June 2026)

- Test HTTPS access via Azure DNS name (from any location)
- Test OpenVPN connectivity to private EC2 IPs
- Verify ELB + Auto Scaling functionality
- Validate CloudWatch alarms trigger SNS email
- Test Lambda snapshot creation in S3 bucket
- Verify IAM least privilege and RBAC MFA

Phase 7: Documentation & Submission - All Members (22-28 June 2026)

- Compile all screenshots (showing settings)
- Write executive summary
- Complete final risk assessment and incident analysis appendices
- Export the final report as a single PDF document for LMS submission
- Submit to LMS by **Sunday, 28 June 2026, 11:59 PM**

Project Submission Guidelines

Item	Requirement
File Format	Single PDF document
Cover Page	Project title, team names, student IDs, submission date
Table of Contents	Required
Diagrams	Labelled architecture diagrams (AWS, Azure, Fortinet)
Screenshots	Each practical step in sequence, showing settings/outputs
Risk Assessment	Table with likelihood, impact, mitigation strategies
Incident Analysis	Security issue identified during testing with detection and response timeline
References	APA format if external sources used
Submission Platform	LMS
Deadline	Sunday, 28 June 2026, 11:59 PM
Academic Integrity	All technical configurations, screenshots, testing evidence, and explanations must be based on the group's own implementation. External sources must be cited using APA or another suitable academic referencing format.

Project Weekly Timesheet

Work	Dates	Task	Hours	Notes
1	11-17 May	Task 1 - Planning, roles, architecture diagram	6	All members contributed
2	18-24 May	AWS VPC, EC2, IAM, RDS setup	8	Geni leads, Yusof and Hari supports
3	25-31 May	AWS ELB, Auto Scaling, Lambda, S3, SNS, CloudWatch, OpenVPN	8	Geni and Hari leads, Yusof supports
4	1-7 June	Azure subscription, RBAC+MFA, Azure AD, DNS	7	Yusof leads, Geni and Hari Supports
5	8-14 June	Fortinet deployment, VPN tunnels, firewall policies + Risk assessment + Incident analysis	8	Geni and Hari worked on Fortinet evidence and risk/incident section, with Yusof supporting where needed
6	15-21 June	Testing (HTTPS, VPN, Load Balancer, monitoring) + Screenshots	7	Hari leads, Yusof and Geni supports
7	22-28 June	Final documentation, report writing, PDF submission	8	All members contributed jointly

Meeting Minutes

Date	Attendees	Summary of Discussion	Action Item
22/05/2026	Yusof Sharifzai, Geni Bahar, Hari Tamang	Initial planning discussion. Group roles, project scope, architecture direction, and task responsibilities were agreed.	Complete Task 1 planning document and confirm AWS/Azure/Fortinet responsibilities.
05/06/2026	Yusof Sharifzai, Geni Bahar, Hari Tamang	Progress review of AWS and Azure implementation. Discussed VPC, EC2, RDS, Azure subscription, RBAC, MFA, and Azure DNS progress.	Continue screenshot collection and verify that each service has labelled evidence.
14/06/2026	Yusof Sharifzai, Geni Bahar, Hari Tamang	Reviewed Fortinet integration, VPN testing, risk assessment planning, and incident scenario selection.	Complete VPN/Fortinet evidence and prepare risk and incident analysis sections.
28/06/2026	Yusof Sharifzai, Geni Bahar, Hari Tamang	Final documentation review. Checked report structure, screenshots, captions, testing results, and PDF submission requirements.	Finalise report, proofread, update table of contents, and export as a single PDF.

Project Scope and Objectives

Area	Details
AWS Services	VPC (public/private subnets, IGW, NAT), EC2, RDS (MySQL), S3 (backups), Lambda (snapshots), ELB + Auto Scaling, ACM (SSL), CloudWatch + SNS, OpenVPN, IAM (least privilege)
Azure Services	Subscription validation, RBAC with MFA, Azure AD tenant, Azure DNS integration
Fortinet	FortiGate firewall, VPN tunnels between AWS and Azure, inspection policies
Security Controls	Encryption at rest (KMS/S3), encryption in transit (SSL/TLS), centralised logging (CloudWatch, CloudTrail, Azure Monitor)
Tagging	All resources tagged with Key = Student_Group_01-FT , Value = Resource identity
Testing and Verification	HTTPS access through Azure DNS, VPN client connectivity, ELB/Auto Scaling validation, CloudWatch/SNS alert testing, Lambda snapshot validation, IAM/RBAC review, and screenshot-based evidence mapping.

Objectives (Measurable goals)

1. Create a fully working website hosted by AWS EC2 with RDS as the back end.
2. Use ELB (Elastic Load Balancer) and Auto-scaling for high-availability purposes.
3. Automate daily snapshots of our EC2 instances using Lambda and store them in an Amazon S3 bucket.
4. Create SNS notification to send emails to the student email address at YooBee when there are any state changes made to an instance running in EC2.
5. Setup Azure Active Directory (AD) tenant and Role Based Access Control (RBAC) along with Multi-Factor Authentication (MFA).
6. Configure Azure DNS records to resolve the public WordPress website through the AWS load balancer endpoint and verify secure HTTPS access from an external client.
7. Deploy Fortinet FortiGate and configure firewall policies, VPN/routing settings, and security controls for inter-cloud traffic management.
8. Document at least 5 identified Risks & Mitigations into a Risk Assessment Table.
9. Write down one documented security incident identified during project testing.
10. Finalise a single PDF report with architecture diagrams, implementation steps, screenshots, testing evidence, risk assessment, incident analysis and verification results.

Risk Management Approach

Risk ID	Owner	Description	Likelihood	Impact	Mitigation Strategy
R1	Geni	IAM misconfiguration leading to privilege escalation	Medium	High	Enforce MFA, least-privilege policies, final project review and permission validation
R2	Geni	VPC misconfiguration (NAT/IGW/routing) causing downtime	Medium	High	Peer review network design, test in stages
R3	Yusof	Azure DNS misconfiguration causing website inaccessible	Low	High	Validate DNS records before final deployment, test with temporary subdomain
R4	Geni/Yusof	VPN tunnel failure between AWS and Azure	Medium	Medium	Redundant VPN tunnels, monitoring alerts on both sides
R5	Hari	Team size reduction	High	Medium	Shared PM responsibilities, weekly check-ins, task redistribution
R6	Geni	Lambda snapshot automation failure	Low	Medium	Test Lambda function in dev environment, enable CloudWatch alerts for execution errors
R7	Geni	FortiGate policy misconfiguration exposing inter-cloud traffic	Medium	High	Peer review of firewall rules, enable logging, test in isolated VPC
R8	Geni	SNS email notification not received by Yoobee student email	Low	Low	Verify email subscription confirmation, test with alternative email

Communication Strategy

Area	Details
Meeting Frequency	Twice weekly: Mondays (planning), Thursdays (progress review) Further dates to be discussed
Primary Tools	Microsoft Teams (meetings, chat), Email (For updates and Work Hours discussion)
Documentation Sharing	Google Docs (shared planning), Teams
Screenshot Storage	If needed: Shared Google Drive folder with subfolders
Progress Tracking	Team message, updated daily and weekly
Tutor Communication	Teams and if required Video/Voice recorded during the meeting, Email
Issue Escalation	Any blocking issue escalated to tutor within 24 hours

Task 2 | Multi-Cloud Project Implementation Using AWS and Azure Cloud Services, with Security Incident Identification and Troubleshooting (Geni)

Task 2: Part-A | Project Implementation using AWS Cloud Services (Geni)

In this section, we documented the AWS side of our implementation. AWS was used as the main platform for hosting the WordPress site. The aim was to create a secure and workable environment first, and then connect it with Azure DNS and Fortinet security controls.

For the AWS setup, we created a custom VPC with public and private subnets. We also configured the main security and support services such as Security Groups, IAM roles, CloudWatch, CloudTrail, S3, Lambda backup automation, OpenVPN, Application Load Balancer, Auto Scaling and ACM for HTTPS. This made the environment closer to a real cloud hosting design rather than only a single EC2 instance.

A key point in the implementation was to avoid exposing every resource directly to the internet. Public-facing components and private components were separated, and access was controlled mainly through Security Groups, NACL review, VPN access and IAM permissions.

Requirement	Evidence included in report
VPC and network segmentation	VPC, public/private subnets, route tables, Internet Gateway, NAT Gateway, Elastic IP, NACLs, and Security Groups
AWS compute and application hosting	EC2 Amazon Linux instance, WordPress deployment, application access testing
Database back end	RDS MySQL deployment, subnet/security group restrictions, snapshot evidence
High availability	Load Balancer, Auto Scaling Group, HTTPS/ACM configuration
Monitoring and notification	CloudWatch monitoring, CloudTrail auditing, SNS email notification
Backup automation	Lambda snapshot automation and S3 backup storage
Secure remote access	OpenVPN client access to private resources
Azure integration	Azure subscription, RBAC/MFA, Azure AD tenant, Azure DNS, VPN/HTTPS testing
Fortinet integration	FortiGate deployment, firewall/security control point, VPN/routing evidence

Testing and verification	HTTPS access, VPN access, monitoring alerts, backup validation, and screenshot evidence
--------------------------	---

AWS Network Architecture

For AWS, we started from the network layer and then added the application and security components. The custom VPC, public/private subnets, Internet Gateway, NAT Gateway, route tables, NACLs and Security Groups form the base of the setup. On top of that, EC2 was used for WordPress and RDS MySQL was used as the database. We also added monitoring, notification and backup services such as CloudWatch, CloudTrail, SNS, Lambda and S3.

Network Security Diagram

The diagram below shows how the AWS network was separated. Public-facing services are placed separately from internal application and database resources. This was important because we did not want the database or internal resources to be directly reachable from the internet.

Virtual Private Cloud (VPC)

We created a dedicated VPC for this assessment so the project resources were kept inside their own network boundary. This became the base for the rest of the AWS configuration.

The VPC was then divided into public and private subnets. This made it easier to control which resources should be public and which resources should stay private.

The screenshot below shows the VPC that was created for the project. All AWS services used in this part of the assessment were built around this network design.

Item	Configuration / Purpose
VPC Purpose	Isolated AWS network for WordPress and supporting services
Public Subnets	Host internet-facing resources such as load balancer/VPN access
Private Subnets	Host internal application/database components
Security Benefit	Reduces attack surface by separating public and private resources
Project Tagging	Resources tagged using group name and resource identity

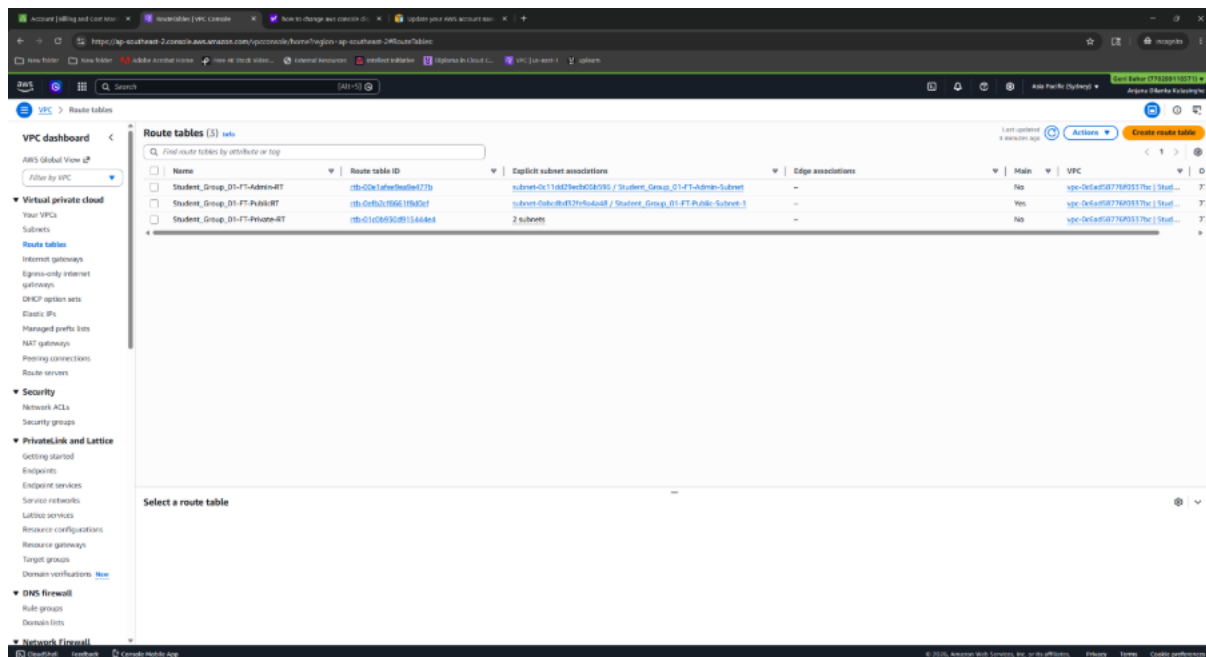

Subnets

The subnets were planned based on how the services need to be accessed. Public subnets are used for resources that need external access, and private subnets are used for internal components such as database or application-side resources. This separation is important because it reduces unnecessary exposure.

Route Tables

Route tables were configured based on the subnet type. Public subnet traffic uses the Internet Gateway, while private subnet traffic uses the NAT Gateway for outbound access. This allows private resources to download updates without making them directly public.

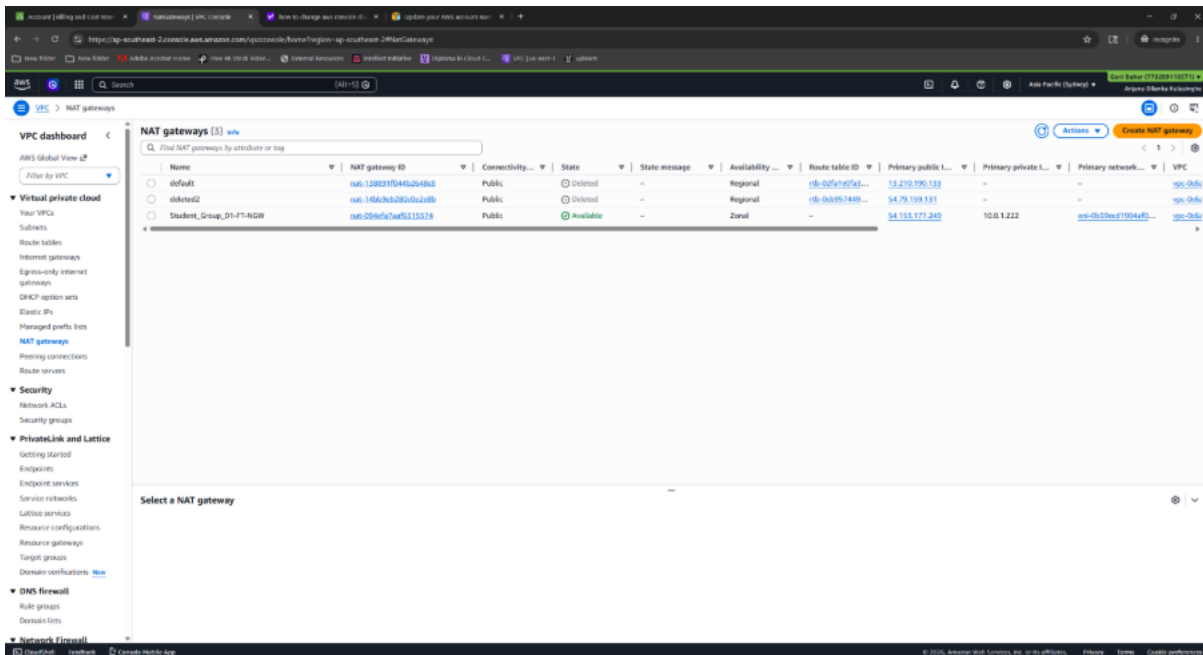

Internet Gateway

The Internet Gateway was attached to the VPC for public subnet connectivity. However, it only works for resources that also have the correct route table and Security Group configuration.

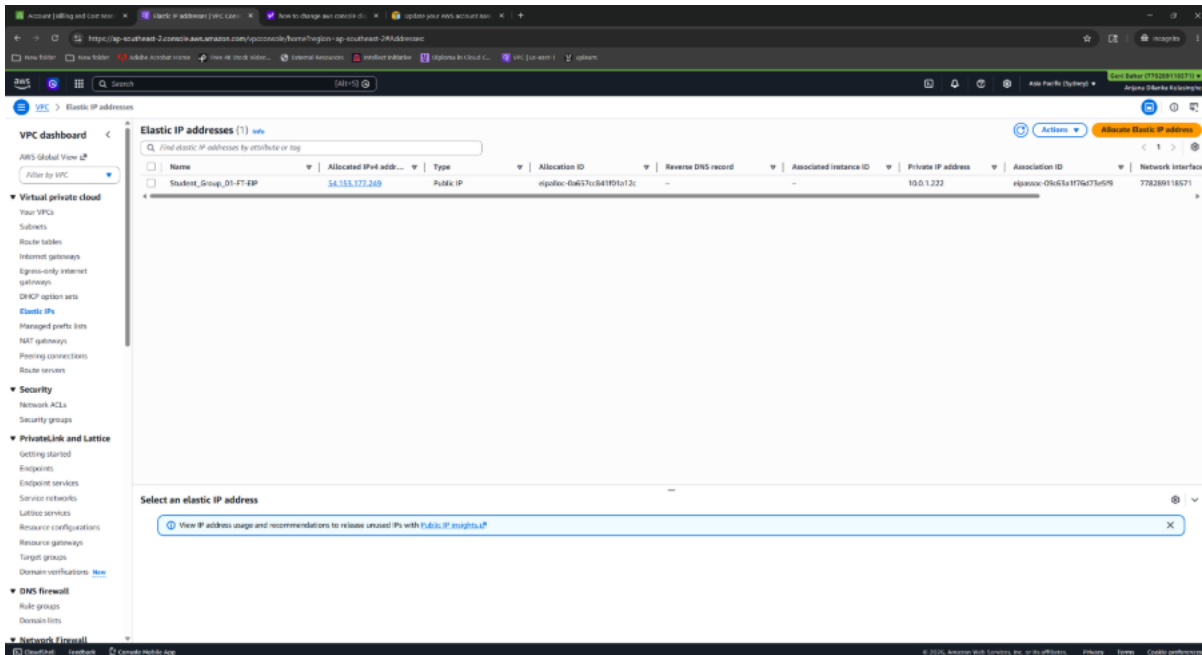

NAT Gateway

The NAT Gateway was used for private subnet outbound traffic. This was needed for updates and package installation, while still avoiding direct inbound access from the internet.

Elastic IP

We allocated an Elastic IP for the NAT Gateway so outbound traffic from private resources had a stable public address.

Network Access Control Lists (NACLs)

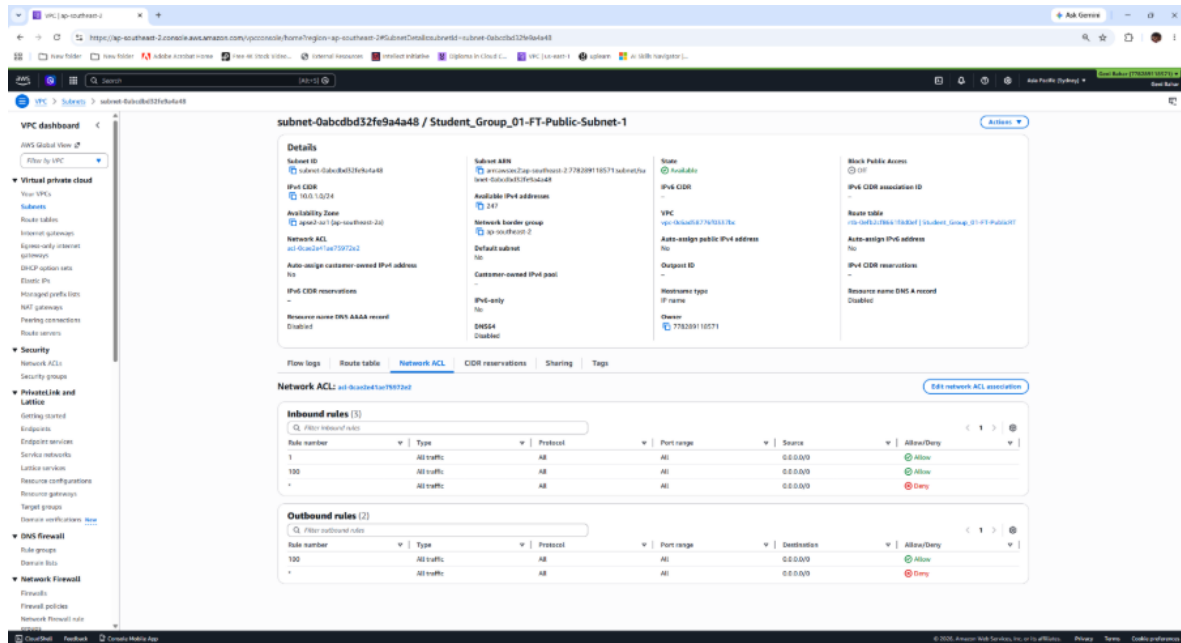

We reviewed the Network ACL configuration as part of the subnet-level security check. In this setup, the default VPC NACL was kept, and Security Groups were used as the main access control method because they are easier to apply directly to EC2, RDS, Load Balancer and VPN resources.

The project subnets use the default VPC Network ACL. This was acceptable for the assessment because Security Groups were used for the more specific access rules.

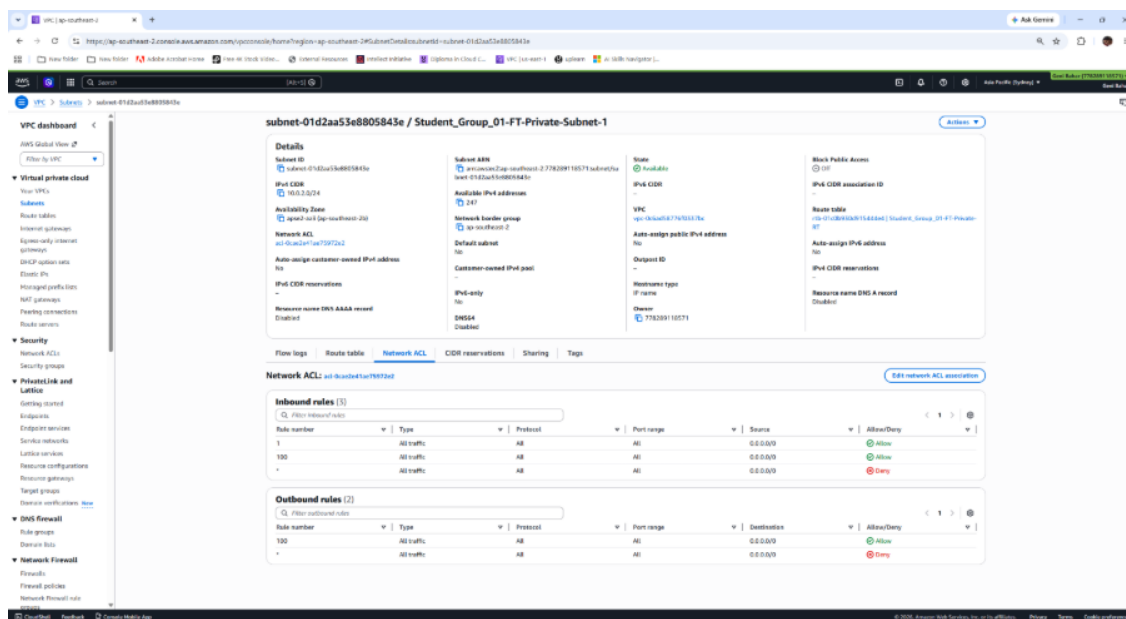

Public Subnet NACL Association

The public subnet NACL association was checked to make sure it was linked correctly to the public subnet used in the design.

Private Subnet NACL Association

The private subnet NACL association was also checked as part of the review. Private resources were still mainly protected using route tables and Security Groups.

Associated Subnets

The screenshot confirms the NACL association with the project subnets.

Security Groups

Security Groups were one of the most important controls in this project. We used separate Security Groups for the Load Balancer, EC2, database and VPN-related resources so each service only allowed the traffic it needed.

The inbound and outbound rules were reviewed carefully because an open rule can quickly become a security issue, especially for SSH or database access.

Security Group	Main inbound access	Security purpose
Load Balancer SG	HTTP/HTTPS from internet	Allows public web access only through the Load Balancer
EC2/Application SG	Web/app traffic from Load Balancer, admin/VPN access only where required	Prevents direct unrestricted access to application servers
RDS SG	MySQL only from approved EC2/Application SG	Prevents public database exposure
VPN/OpenVPN SG	VPN ports from authorised clients	Supports secure private administration
FortiGate SG	VPN/firewall-related traffic only	Controls inter-cloud traffic and security inspection

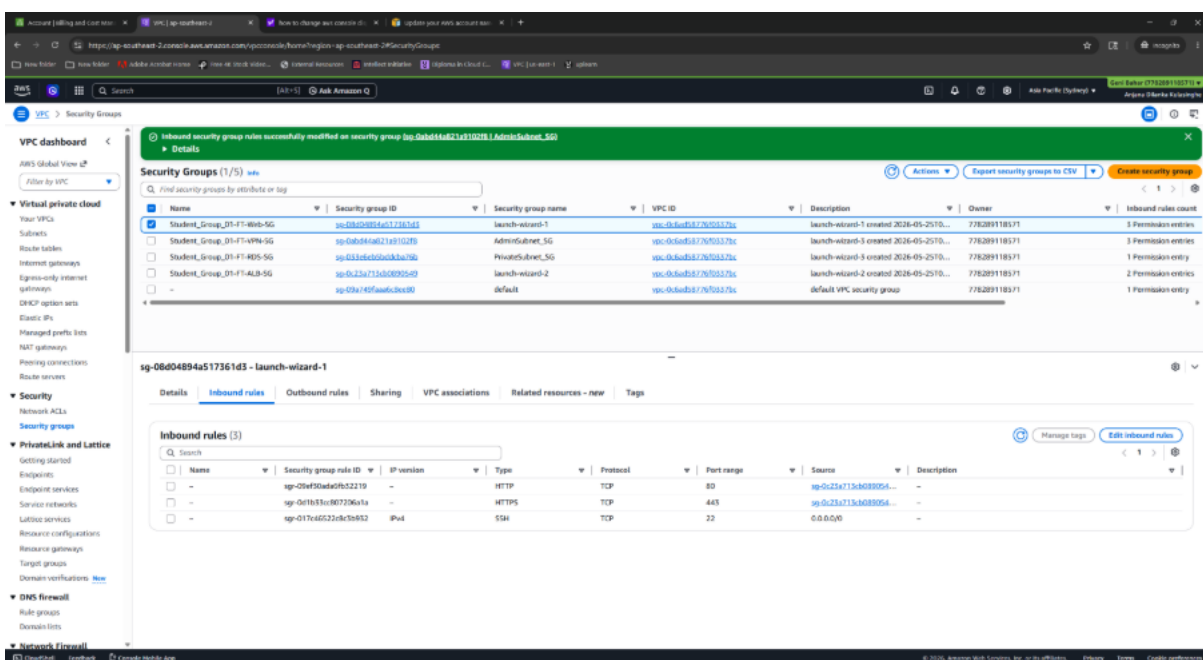

Inbound/Outbound Rules

The Application Load Balancer Security Group allows HTTP and HTTPS from the internet because it is the public entry point for the WordPress site.

The EC2 Security Group was used to limit direct access to the application instances and keep administration access controlled.

The database Security Group restricts MySQL access so the database is not open directly to the public internet.

The VPN Security Group supports remote access, but only through the required VPN-related ports.

Security Groups (1/5)

Name	Security group ID	Security group name	VPC ID	Description	Owner	Inbound rules count
Student_Group_01-TT-WEB-SG	sg-0b6d44b21a9102f8	launch-wizard-1	vpc-0c5ad5b776503379c	launch-wizard-1 created 2026-05-25T0...	776289118371	3 Permission entries

Identity and Access Management (IAM)

For IAM, we used roles instead of keeping long-term access keys inside instances or scripts. This is a safer approach because services can receive only the permissions they need. The EC2 role was used for controlled S3 access, and the Lambda role was used for snapshot automation.

The screenshot shows the AWS IAM console interface for the role **Student_Group_01-FT-EC2-S3-Role**. The left sidebar contains navigation links for Identity and Access Management (IAM), Access Management, Access reports, and related services. The main content area displays the role's summary, including its creation date (May 26, 2020), ARN, and instance profile ARN. Below the summary, there are tabs for Permissions, Trust relationships, Tags, Last Accessed, and Revoke sessions. The Permissions tab is active, showing a list of permissions policies attached to the role. The list includes **AWSManagedReadOnlyAccess**, **CloudWatchAgentServerPolicy**, and **Student_Group_01-FT-S3-Backup-Bucket-Access**. A section for 'Generate policy based on CloudTrail events' is also visible at the bottom.

This screenshot shows the same AWS IAM console interface, but with the JSON policy for the **Student_Group_01-FT-S3-Backup-Bucket-Access** policy expanded. The policy is a JSON document that grants permissions to manage S3 buckets and objects. The JSON content is as follows:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ListBackupBucketOnly",
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::student-group-01-ft-backups"
    },
    {
      "Sid": "ReadWriteObjectToBackupBucketOnly",
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::student-group-01-ft-backups/*"
    }
  ]
}

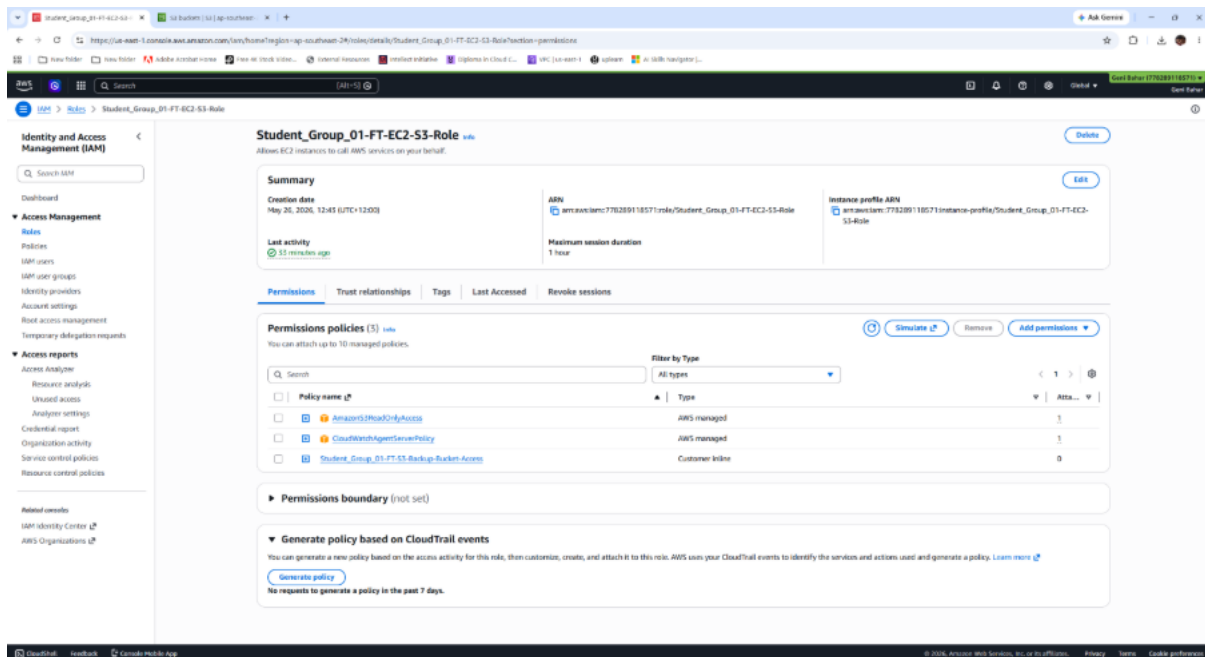

```

The interface also shows buttons for 'Copy JSON' and 'Edit' next to the policy name.

EC2 and S3

The EC2 IAM role allows the application server to access S3 without storing access keys directly on the instance.

The screenshot displays the AWS IAM console interface. On the left, the 'Identity and Access Management (IAM)' sidebar is visible, showing options like 'Dashboard', 'Access Management', 'Access reports', and 'Related services'. The main content area is titled 'Permissions policies' and shows a list of policies. The selected policy is 'Student_Group_01-FT-S3-Backup-Bucket-Access', which is displayed in a JSON format. Below the policy details, there is a 'Permissions boundary' section and a 'Generate policy based on CloudTrail events' section. The bottom of the screenshot shows the 'Student_Group_01-FT-EC2-S3-Role' page, which includes a 'Summary' section with creation date, ARN, and last activity, as well as a 'Trusted entities' section showing the policy's JSON structure.

Lambda to access EC2

The Lambda execution role provides the permissions required for automated EBS snapshot creation.

The first screenshot shows the 'Summary' tab of the 'Student_Group_01-FT-Lambda-Snapshot-Role'. The role was created on May 20, 2025, at 12:49 (UTC+12:00). Its ARN is 'arn:aws:iam::775228911857:role/Student_Group_01-FT-Lambda-Snapshot-Role' and its maximum session duration is 1 hour. The 'Permissions policies' tab shows three attached policies: 'AmazonEC2FullAccess', 'AmazonS3FullAccess', and 'CloudWatchLogsFullAccess', all of which are AWS managed.

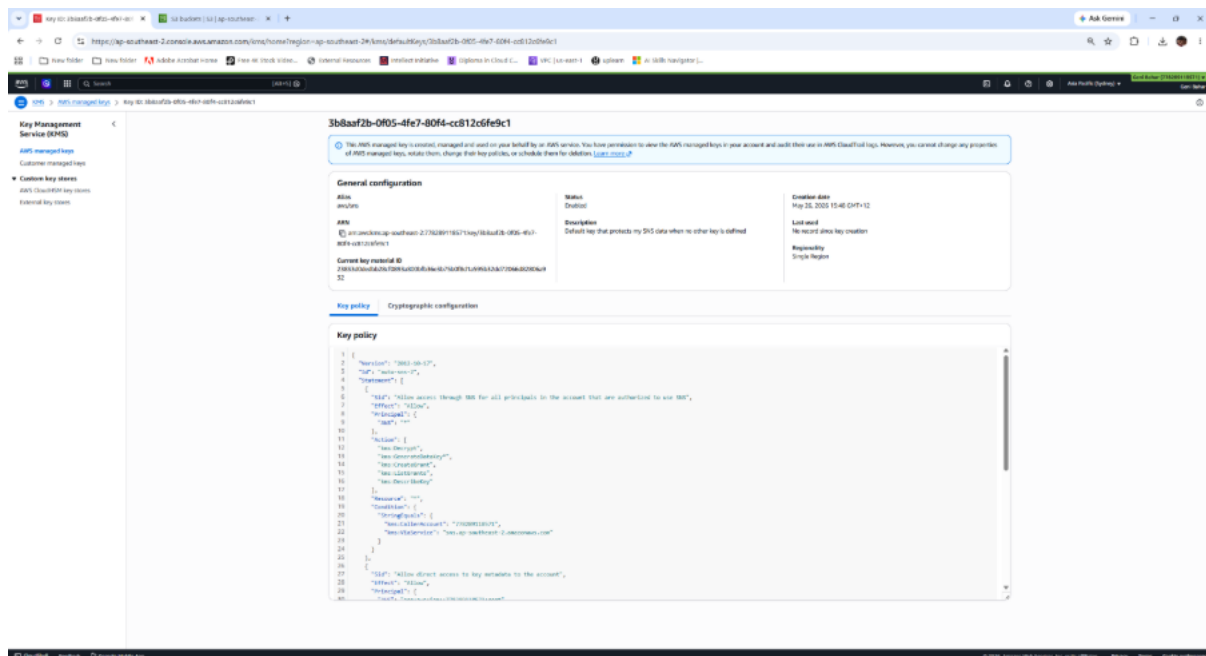

The second screenshot shows the 'Trust relationships' tab for the same role. It displays the 'Trusted entities' section with a JSON policy document that allows the role to assume the role 'arn:aws:iam::775228911857:role/Student_Group_01-FT-Lambda-Snapshot-Role' from the service 'lambda.amazonaws.com'.

```

1: {
2:   "Version": "2012-10-17",
3:   "Statement": [
4:     {
5:       "Effect": "allow",
6:       "Principal": {
7:         "Service": "lambda.amazonaws.com"
8:       },
9:       "Action": "sts:assumeRole"
10:    }
11:  ]
12: }
  
```

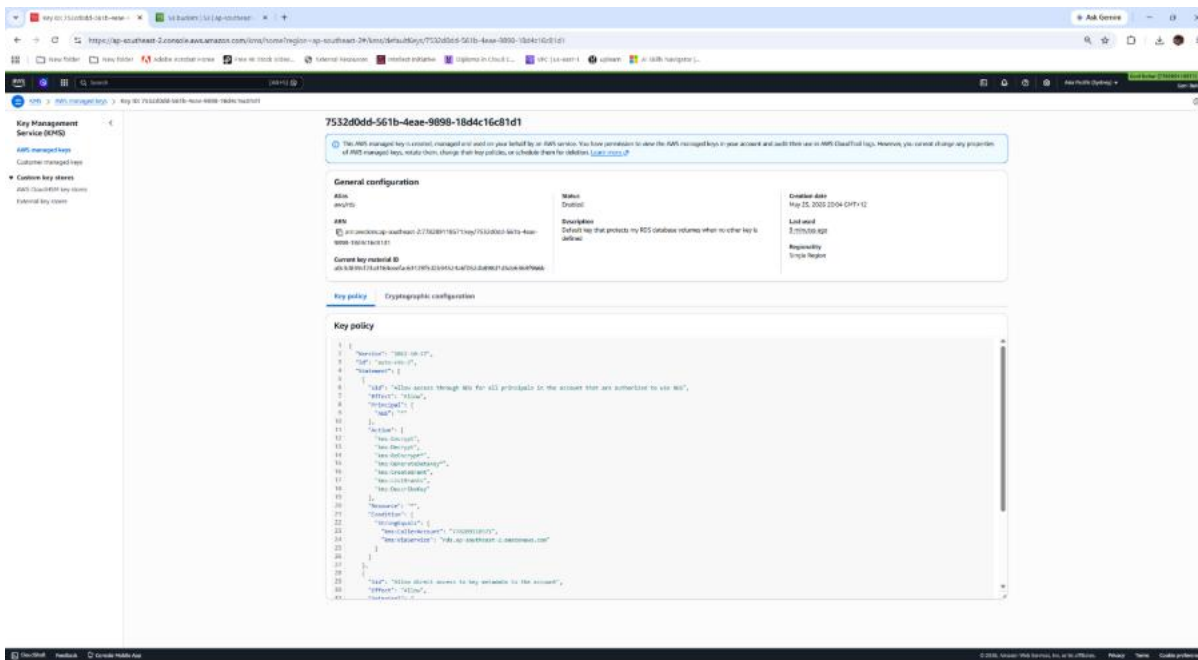

AWS KMS Encryption

AWS KMS was reviewed and used for encryption-related protection in the AWS environment. For this assessment, we focused on making sure storage and database services were encrypted where possible.

The screenshot shows the AWS IAM console interface. On the left, there's a navigation menu with 'Key Management Service (KMS)' selected. The main content area displays the details for a specific AWS managed key. The key ID is '2e952c15-8c7d-4a82-a599-6c5ae97b0910'. The key is in the 'Enabled' state. The description is 'Default key that protects my ACM private keys when no other key is defined'. The creation date is 'Jan 05, 2023 23:05 CDT-12'. The last used date is not specified. The key is associated with the 'us-east-1' region. Below the general configuration, there's a 'Key policy' section with a JSON policy document. The policy grants 'kms:Decrypt' and 'kms:DescribeKey' permissions to the 'arn:aws:iam::123456789012:role/KeyPolicyRole' principal.

The screenshot shows the AWS IAM console interface. On the left, there's a navigation menu with 'Key Management Service (KMS)' selected. The main content area displays the details for a specific AWS managed key. The key ID is '07745d75-91b1-4d00-bc16-dc9c34b315d6'. The key is in the 'Enabled' state. The description is 'Default key that protects my Secrets Manager data when no other key is defined'. The creation date is 'May 25, 2023 20:04 CDT-12'. The last used date is '2/28/23 10:00'. The key is associated with the 'us-east-1' region. Below the general configuration, there's a 'Key policy' section with a JSON policy document. The policy grants 'kms:Decrypt', 'kms:DescribeKey', and 'kms:GenerateDataKey' permissions to the 'arn:aws:iam::123456789012:role/KeyPolicyRole' principal.

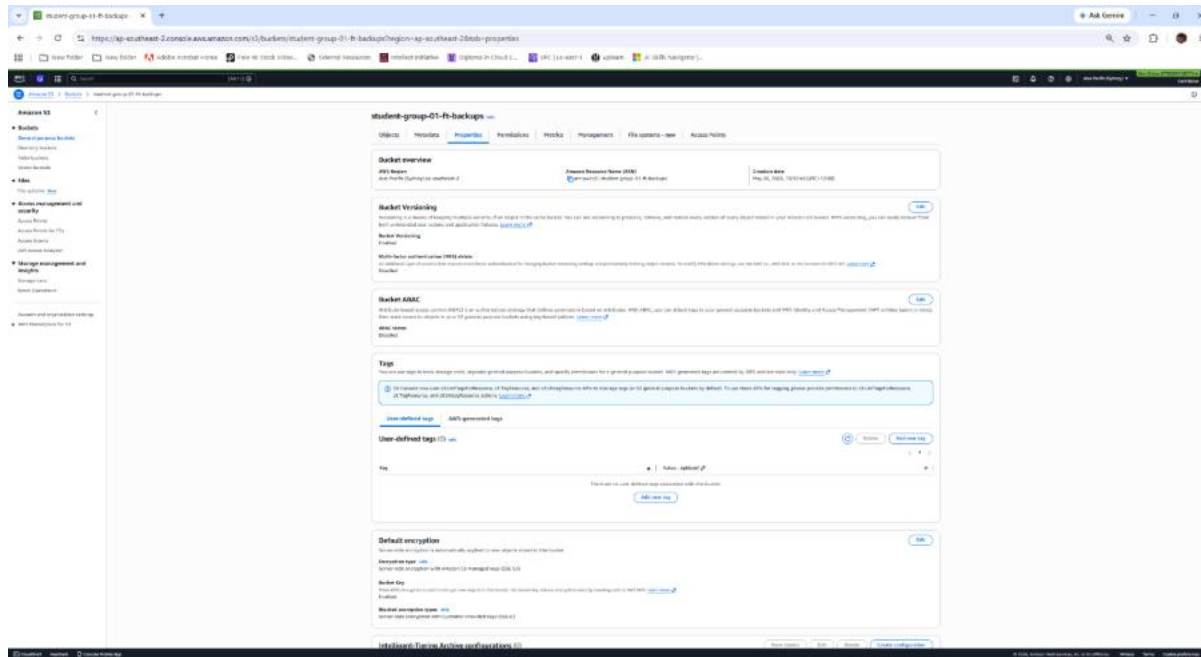

S3

The S3 bucket was used as part of the backup design. Since this bucket is used for backup data, public access is not required and should remain blocked.

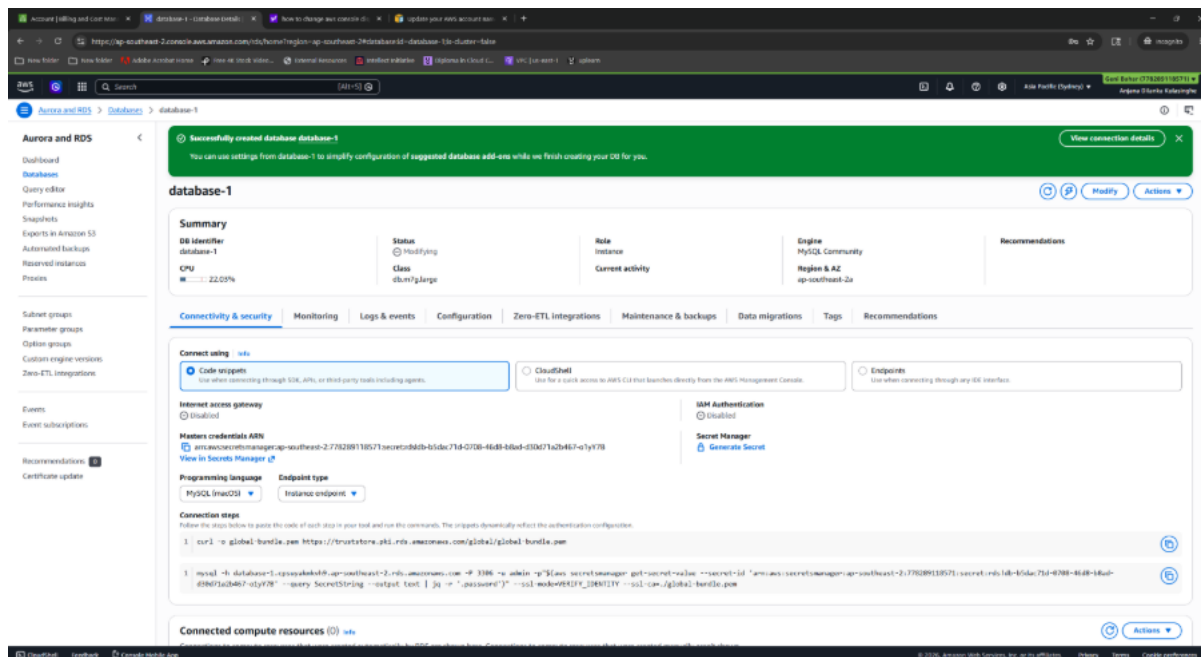

S3 Backup Encryption

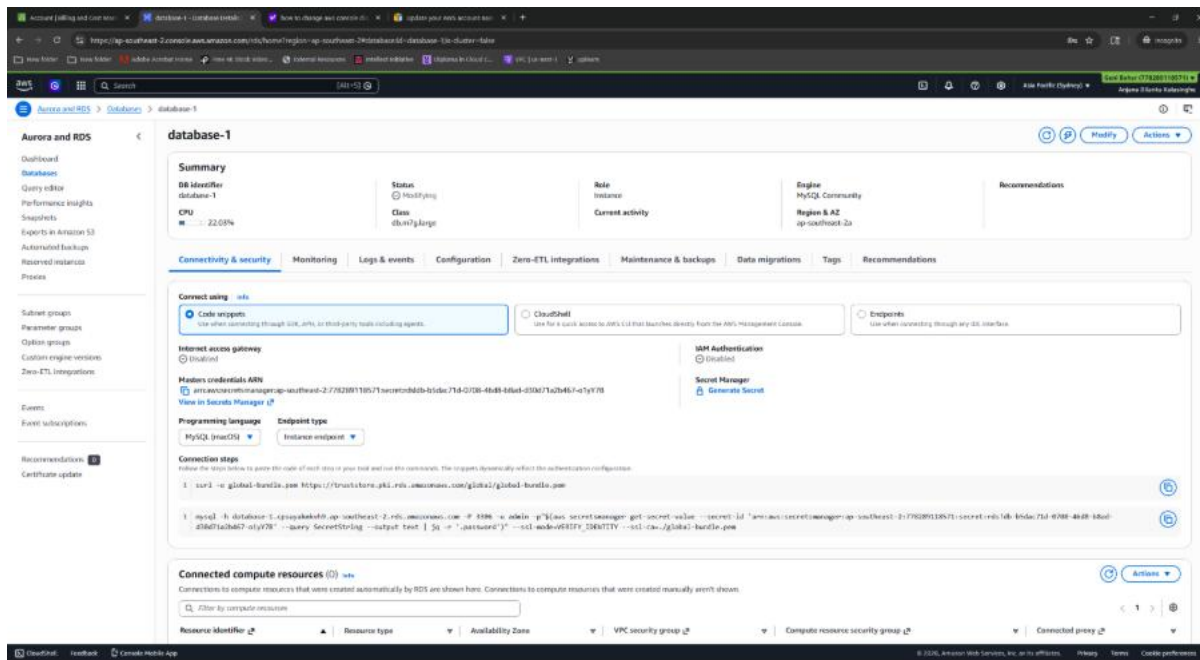

Server-side encryption was enabled for the S3 backup bucket. This helps protect backup data at rest.

RDS

RDS was configured as the database back end for WordPress. The database should stay private and should only accept traffic from the application layer through Security Group rules.

RDS Encryption

Encryption was enabled on the RDS instance using AWS managed keys. This protects the database storage, backups and snapshots.

Snapshots

Snapshots were included so the environment has a recovery point if something is deleted or misconfigured. This was an important part of the backup and recovery plan.

High Availability Architecture

To improve availability, we configured an Application Load Balancer and Auto Scaling Group.

The Load Balancer distributes traffic to healthy instances, and Auto Scaling helps replace unhealthy instances or support extra capacity when needed.

Component	High availability contribution
Application Load Balancer	Distributes web traffic and provides a stable public entry point
Auto Scaling Group	Replaces unhealthy instances and adjusts capacity based on demand
Multiple subnets	Supports deployment across separate network segments
RDS	Provides managed database hosting and snapshot capability
DNS/HTTPS	Provides stable and secure public access

Target Group

The target group was used to register the WordPress instances and check whether they were healthy before sending traffic.

The first screenshot shows the 'Launch Templates' page in the AWS Management Console. It displays a table with one launch template: 'Student_Group_01-FT-WordPress-LT'. The details for this template are shown below, including its version (1), AMI ID (ami-0240b262f6d108ae3), and various configuration options like instance type (t3.micro) and security groups.

The second screenshot shows the 'Target Groups' page. It displays a target group named 'Student-Group-01-FT-TG'. The details section shows the target type as 'Instance', the protocol as 'HTTP', and the port as '80'. The 'Registered targets' table lists four targets, all of which are 'Healthy'.

Instance ID	Name	Port	Zone	Health status	Health status details	Administrative o...	Override details	Launch...	Anomaly
i-030e298f738a1a204	Student_Group...	80	ap-south-east-1	Healthy	-	No override	No override is current...	May 23, 2...	Normal
i-040929e3f3081a809	Student_Group...	80	ap-south-east-1	Unhealthy	Target deregistration...	No override	No override is current...	May 26, 2...	Normal
i-07363433353636085	Student_Group...	80	ap-south-east-1	Unhealthy	Target deregistration...	No override	No override is current...	May 26, 2...	Normal
i-0a5176a15050a54290	Student_Group...	80	ap-south-east-1	Unhealthy	Target deregistration...	No override	No override is current...	May 23, 2...	Normal

Load Balancer

The Application Load Balancer distributes requests across available instances to improve availability.

The first screenshot displays the 'Details' tab for the 'Student-Group-01-FT-ALB' load balancer. Key information includes:

- Load balancer type:** Application
- Scheme:** Internet-facing
- Status:** Active
- Hosted zone:** 21GHS0264ZPN465
- VPC:** vpc-02d656779f0287bc
- Availability Zones:** us-east-2a (ip-2018-01-1020013b), us-east-2b (ip-2018-01-1020013b), us-east-2c (ip-2018-01-1020013b)
- Load balancer ARN:** arn:aws:elasticloadbalancing:us-east-2:778289118571:loadbalancer/app/Student-Group-01-FT-ALB/11f10ba3-97a7-4a6b-b8d1-27a0a0a0a0a0
- DNS name:** Student-Group-01-FT-ALB-673220005.ap-southeast-2.elb.amazonaws.com (A Record)

The second screenshot displays the 'Resource map' tab for the same load balancer, showing its architecture:

- Listeners (2):** HTTPS-443 and HTTP-80.
- Rules (2):** Both listeners have a single rule that forwards traffic to the target group.
- Target group (1):** Named 'Student-Group-01-FT-TG', it contains one target: 'i-006080188c1a2076' (Port 80).
- Targets (1):** The target is shown as 'Healthy'.

Auto Scaling Group

The Auto Scaling Group manages instance capacity and can replace unhealthy instances.

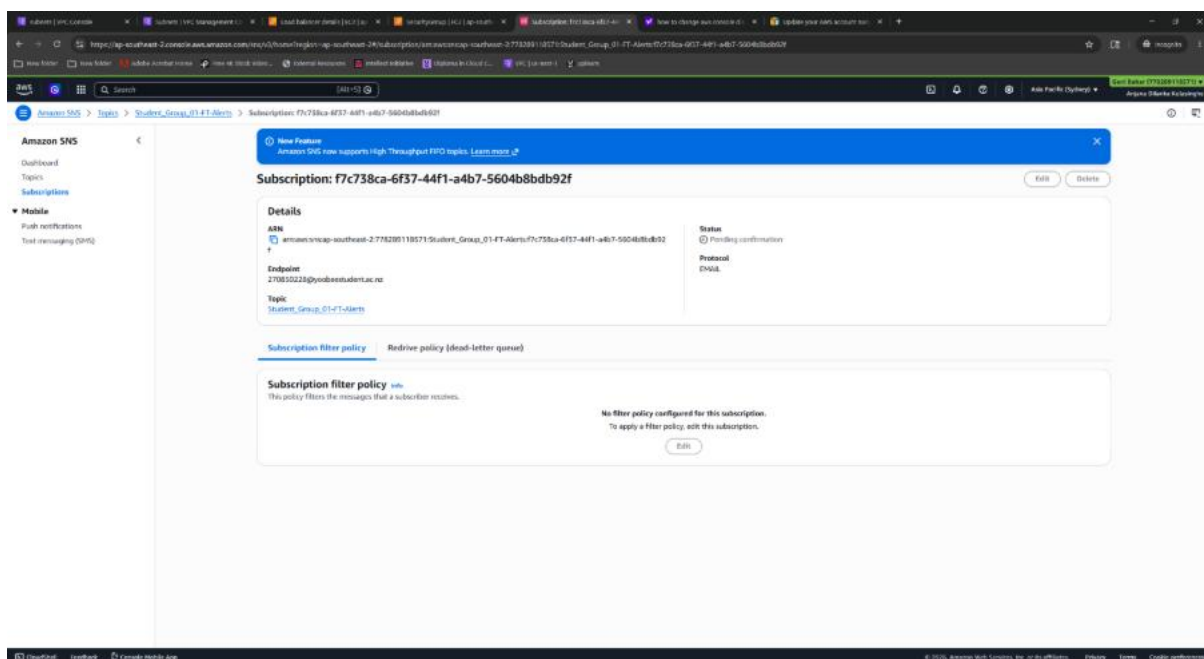

The screenshot displays the AWS Management Console interface for an Auto Scaling Group. The top navigation bar shows the 'Auto Scaling groups' page with a list of groups. The selected group, 'Student_Group_01-FT-ASG', is shown in detail. The 'Capacity overview' section indicates a desired capacity of 2 instances, with scaling limits set to 1-2. The 'Launch template' section shows the template 'Student_Group_01-FT-WordPress-LT' with an AMI ID of 'ami-024058294a7d6627' and an instance type of 't2.micro'. The 'Network' section shows the group is associated with the 'ap-southeast-2' region and the 'ap-southeast-2b' availability zone. The 'Instance type requirements' section shows the group is configured for 'On-Demand' instances. The 'Health checks' section shows the group is configured with 'EC2' health checks and a '200' health check grace period. The 'Instance maintenance policy' section shows the group is configured with a 'No policy' replacement behavior. The 'Capacity Reservation preference' section shows the group is configured with a 'No preference' capacity reservation preference.

Monitoring and Logging

Monitoring and logging were implemented to support operational visibility and incident detection. CloudWatch was used to monitor EC2 state changes and trigger alerts through SNS. CloudTrail was included to support audit visibility for AWS API activity, such as configuration changes, access attempts, and administrative actions. Together, CloudWatch and CloudTrail improve the team's ability to detect operational issues and investigate potential security incidents.

SNS

Amazon SNS was configured as the notification service for operational alerts. The service distributes monitoring notifications to subscribed recipients whenever configured events or alarms are triggered.

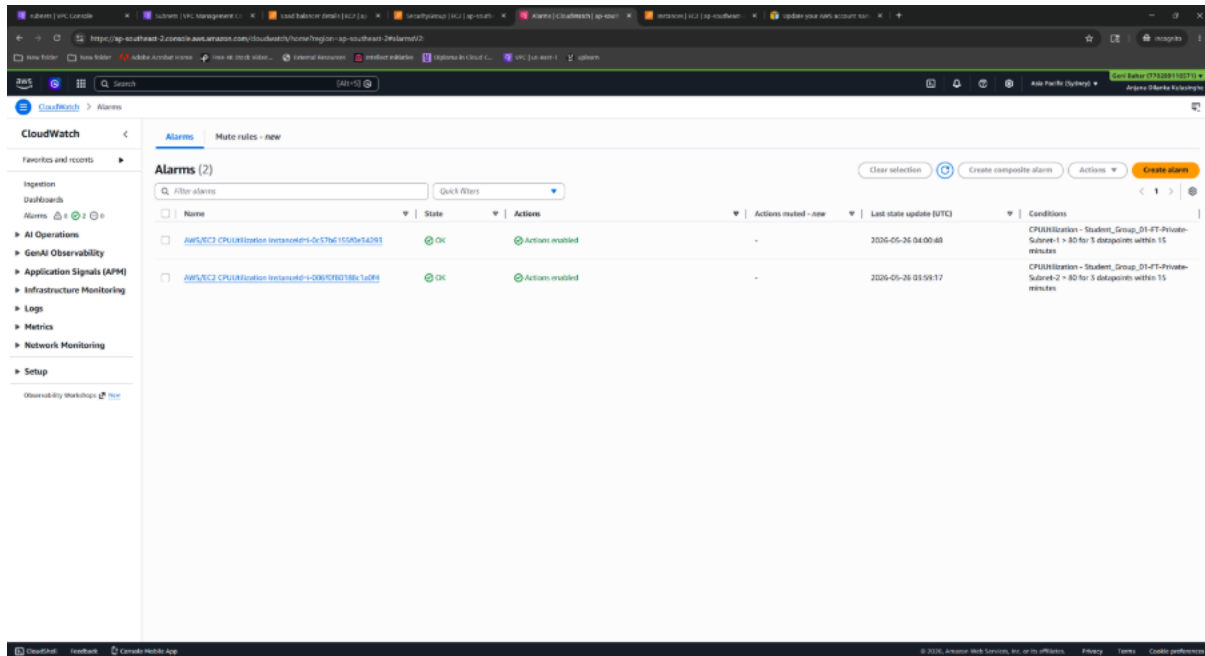

Alert Confirmation

The screenshot confirms successful subscription and delivery of SNS notifications. This validates that monitoring alerts can be received by the project team when required.

CloudWatch Alerts

CloudWatch alarms were configured to monitor selected AWS resources and operational metrics. These alarms provide proactive visibility into infrastructure health and trigger notifications when predefined thresholds are exceeded.

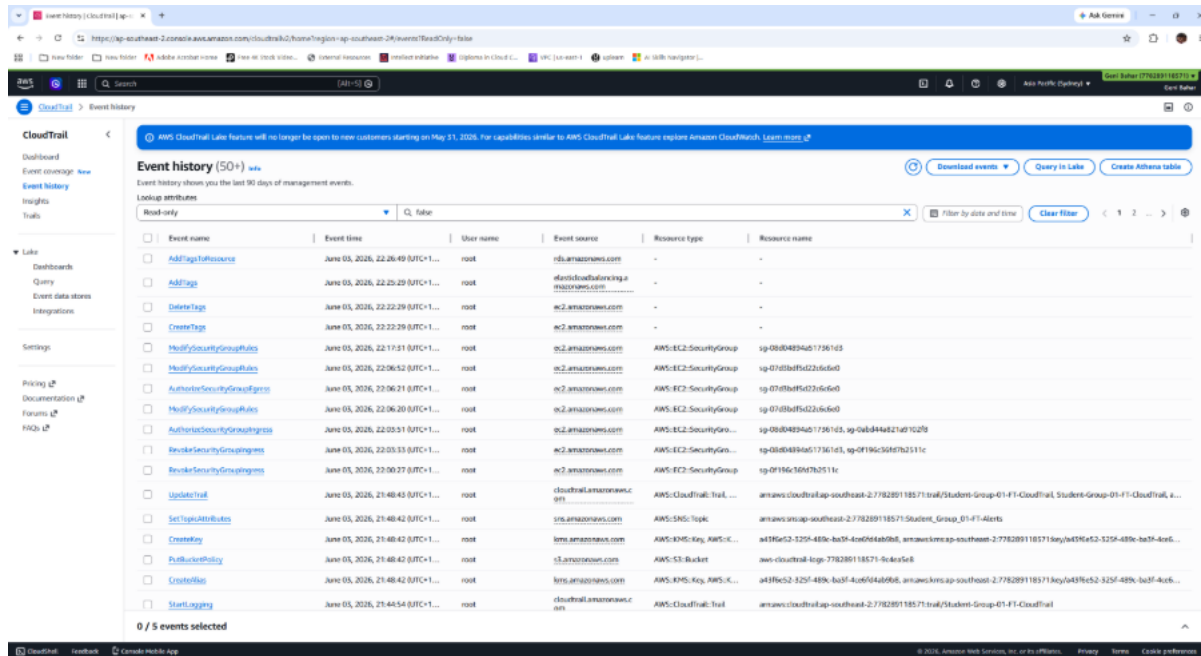

CloudTrail Auditing

AWS CloudTrail was enabled to provide audit logging and account activity tracking. CloudTrail captures API activity across the AWS environment and stores audit records for security monitoring, compliance reporting, and troubleshooting purposes.

CloudTrail logging was configured to store audit data within Amazon S3 while Event History was used to validate successful activity capture.

Event History

CloudTrail Event History was reviewed to verify successful logging of AWS management activities. The recorded events demonstrate that account actions are being captured for auditing and monitoring purposes.

The screenshot shows the AWS CloudTrail console's Event History page. The page displays a list of events with columns for Event name, Event time, User name, Event source, Resource type, and Resource name. The events listed include actions like 'AddTagsToResource', 'DeleteTags', 'CreateTags', 'ModifySecurityGroupRules', 'AuthorizeSecurityGroupEgress', 'RevokeSecurityGroupEgress', 'UpdateTrail', 'SetTagsAttributes', 'CreateKey', 'PublishEventHistory', 'CreateRole', and 'StartLogging'. The events are filtered by date and time, and the page shows 0 / 5 events selected.

Event name	Event time	User name	Event source	Resource type	Resource name

Secure Remote Access

OpenVPN was used to support secure administrative access to private AWS resources without exposing management ports directly to the public internet. This approach reduces the risk of brute-force attacks and unauthorised access by requiring users to connect through a VPN client before reaching internal resources.

OpenVPN Setup

OpenVPN Access Server was deployed to provide secure remote access to AWS resources located within private subnets. The solution allows authorized users to establish encrypted VPN connections and access internal services securely.

The first screenshot shows the AWS Marketplace product page for 'OpenVPN Access Server / Self-Hosted VPN (BYOL)'. The page includes a product overview, highlights, and a 'Launch' button. The second screenshot shows the 'Launch OpenVPN Access Server / Self-Hosted VPN (BYOL)' wizard, which provides a summary of the instance configuration and next steps.

Product Overview:

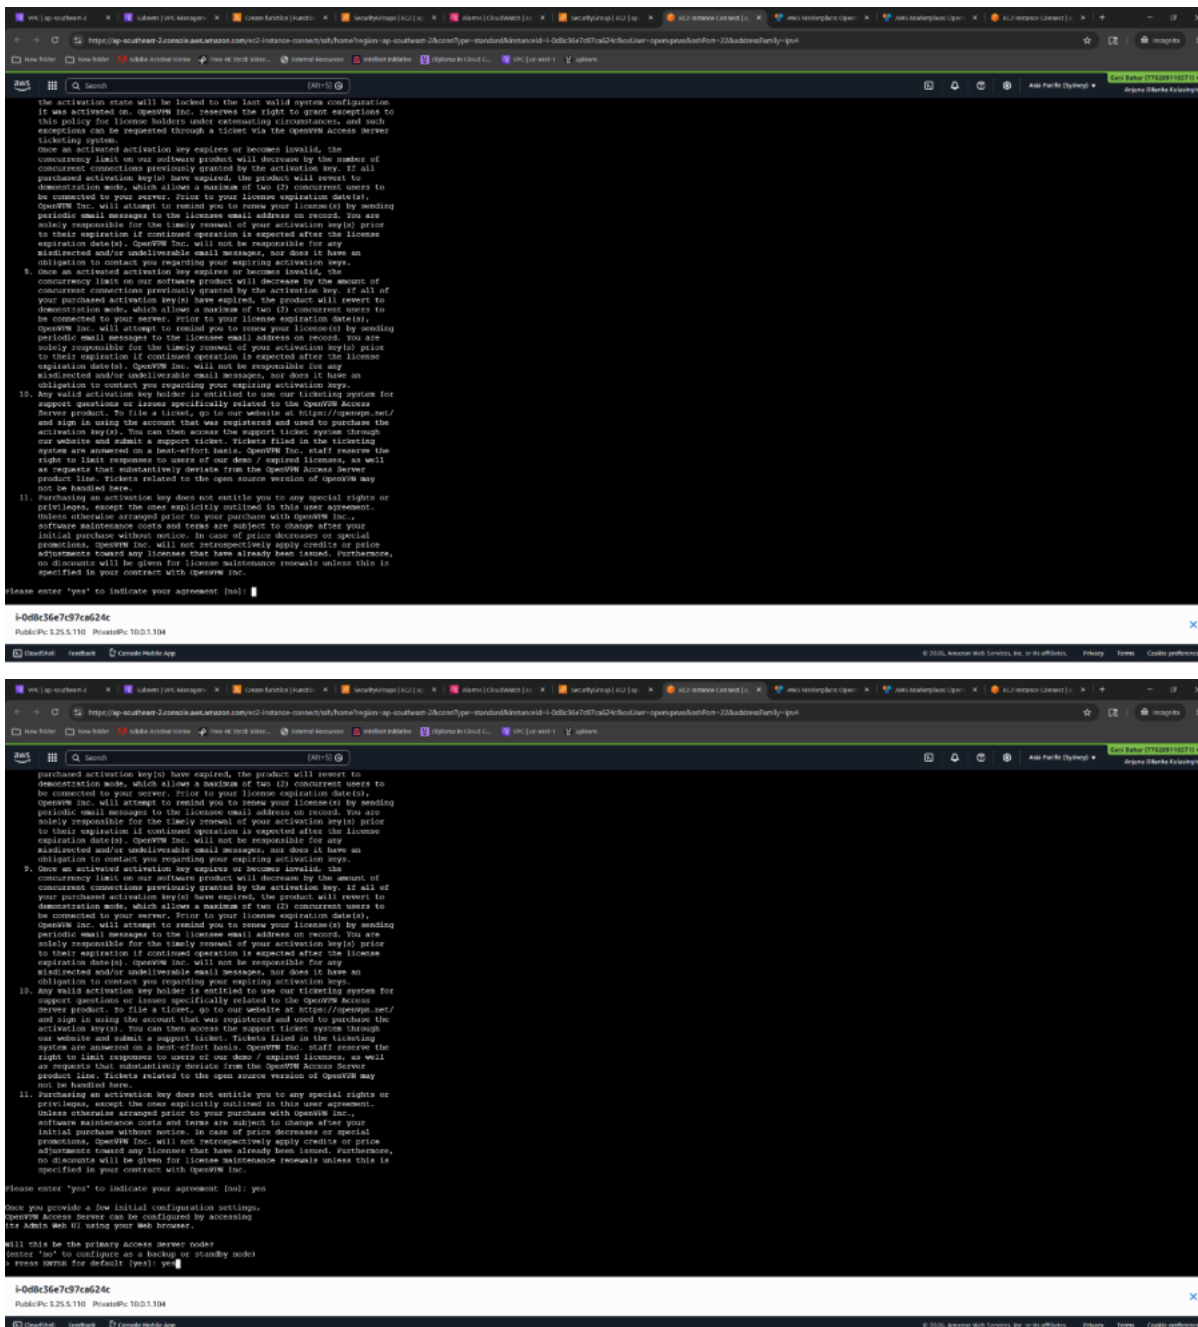

- Secure Network Access:** A self-hosted, scalable secure remote access, site-to-site VPN solution that gives your employees the freedom to work securely with end-to-end encryption for accessing SaaS, the internet, and company resources. Essential security controls needed to enable from a trusted perimeter security model to an identity-based ZTNA approach.
- OpenVPN Client Software:** OpenVPN client software that accommodates Windows, macOS, Linux, Android, iOS, and ChromeOS environments. Includes a built-in local authentication system and support for authentication with Active Directory, PAM, LDAP, RADIUS, SAML, and even a custom Python-based authentication module is possible.

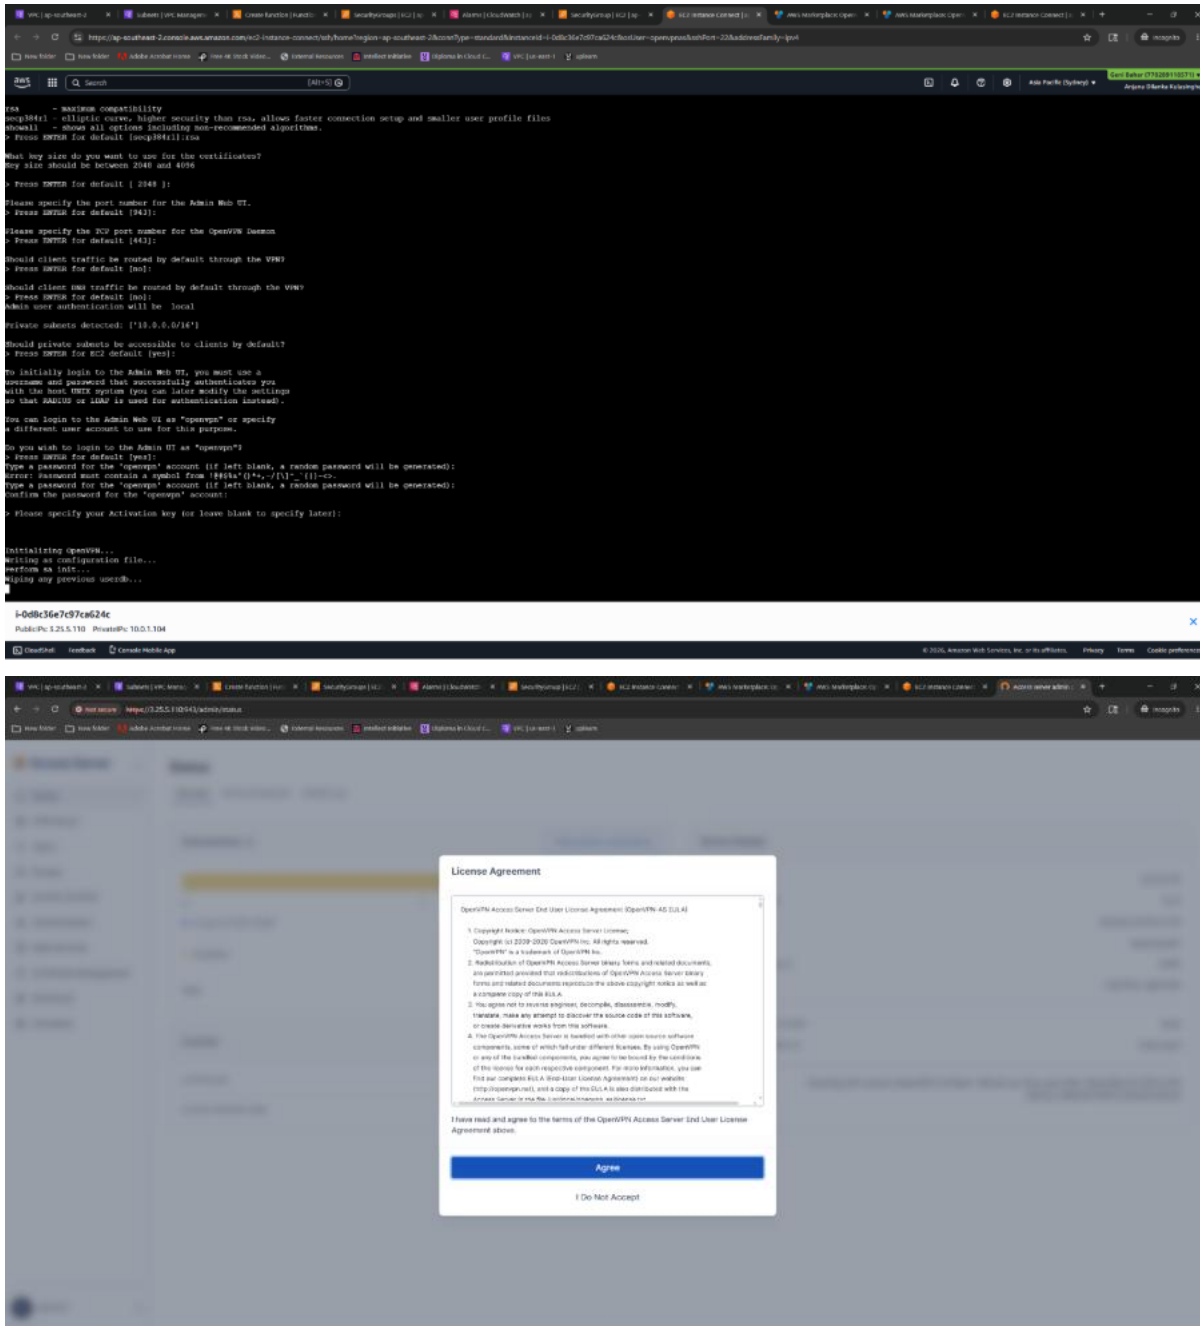

Launch Summary:

Instance ID	Region	VPC	Security group
i-0d8b55e7c370a234c	ap-south-2	sg-056ef8677a03337bc	sg-0708b75d23c6c6d
AMI ID	Software version	Subnet	Key pair
ami-0af699f38bc48a6	5.1.0	subnet-b4be3d327c9a446	Student_Group_01-F1_KP
AMI alias	EC2 instance type		
jfnachindia/marketplace/prod-openssl-2.1.0	t2.small		

Next steps:

- Vendor's Launch and connection instructions:** For instructions on using the OpenVPN Access Server appliance on the AWS Marketplace, please visit <https://openvpn.net/vpn-server-resources/amazon-web-services-ec2-byol-appliance-quick-start-quick/>.
- Launch more instances:** Use the same settings or set up a new instance. [Launch more instances](#)
- Manage your subscription:** Upgrade, cancel, or manage access to your subscription. [Manage subscription](#)

The top screenshot displays the 'VPN Server' configuration page in the OpenVPN Access Server interface. The 'Server Address' field is set to '3.25.5.110'. The 'Interface' is set to 'eth0'. Under 'OpenVPN daemons', the 'Protocol' is set to 'TCP and UDP', the 'UDP Port' is '1194', and the 'TCP Port' is '443'. The bottom screenshot shows the 'Get connected' page, which provides instructions for downloading the OpenVPN Connect client for Windows and a mobile app. The mobile app interface shows a connection profile for 'openvpn@3.25.5.110' and a 'Connect' button.

The screenshot confirms successful VPN connectivity between the client device and the AWS environment. Once connected, internal resources become accessible through private network addresses.

VPN Connectivity Validation

Open VPN test (Connect to Web EC2 with VPN)

Connectivity testing confirmed that authorized users can access internal AWS resources after establishing a VPN connection. This validates the effectiveness of the secure remote access implementation.

```

Command Prompt - ssh -i x + v
C:\Users\64220\Desktop>ssh -i "Student_Group_01-FT_KP.pem" ec2-user@10.0.2.230

Amazon Linux 2023

https://aws.amazon.com/linux/amazon-linux-2023

[ec2-user@ip-10-0-2-230 ~]$ |

```

The screenshot displays the AWS Management Console for the 'us-east-1' region. The 'Instances' page shows a list of EC2 instances. One instance, 'Student_Group_01-FT-EC2-1', is selected. A terminal window is open, showing the command 'ssh -i "Student_Group_01-FT-XP.pem" ec2-user@10.0.2.230' and its output, which indicates a connection timeout. The terminal also shows the command 'ssh -i "Student_Group_01-FT-XP.pem" ec2-user@10.0.2.230' and its output, which indicates a connection timeout. The terminal also shows the command 'ssh -i "Student_Group_01-FT-XP.pem" ec2-user@10.0.2.230' and its output, which indicates a connection timeout.

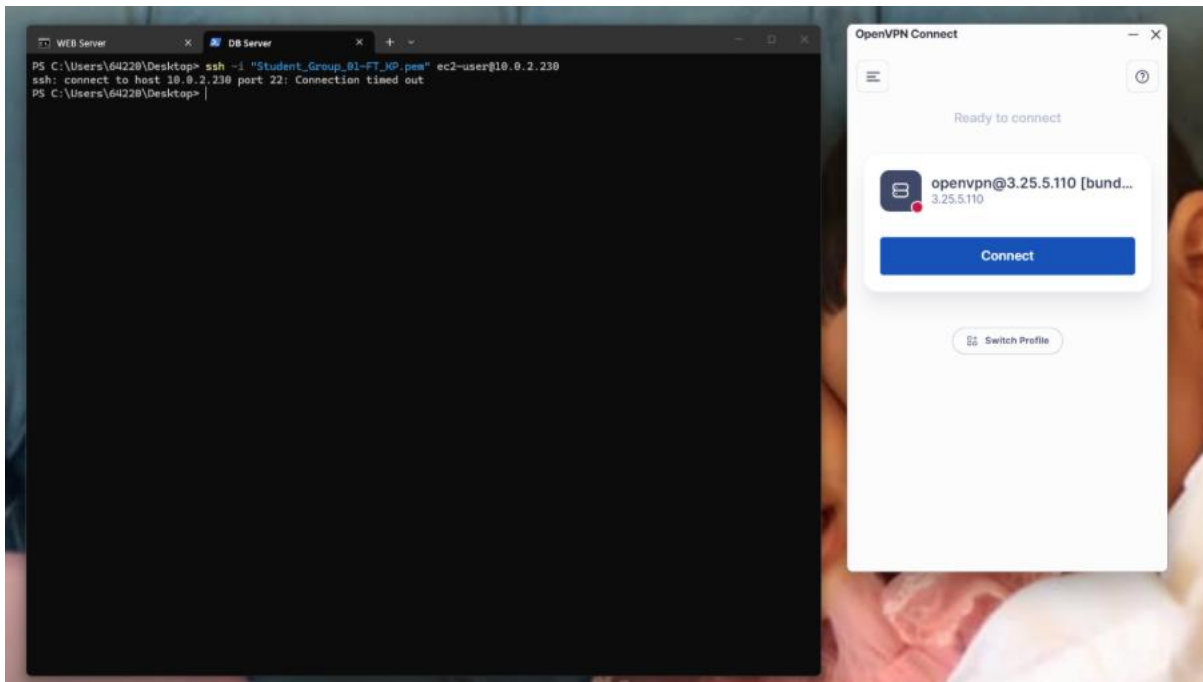

Without VPN

The tests demonstrate that private AWS resources cannot be accessed directly from the public internet. This confirms that network segmentation and security controls are functioning as intended.

Connect to Web Server

The screenshot shows a terminal window with the command 'ssh -i "Student_Group_01-FT-XP.pem" ec2-user@10.0.2.230' and its output, which indicates a connection timeout. The terminal also shows the command 'ssh -i "Student_Group_01-FT-XP.pem" ec2-user@10.0.2.230' and its output, which indicates a connection timeout. The terminal also shows the command 'ssh -i "Student_Group_01-FT-XP.pem" ec2-user@10.0.2.230' and its output, which indicates a connection timeout. An OpenVPN Connect window is also visible, showing the connection status and a 'Connect' button.

Connect to Private Application Server

With VPN

After establishing the VPN connection, access to private resources was successfully restored. This validates that secure access is available only through authorised VPN channels.

Connect to Web Server

Connect to Private Application Server

Backup Automation

Lambda was used to automate snapshot creation so that backups are not dependent on manual action. The function is triggered on a schedule and uses an IAM role with the required EC2 snapshot permissions. CloudWatch logs should be used to validate execution success or troubleshoot errors.

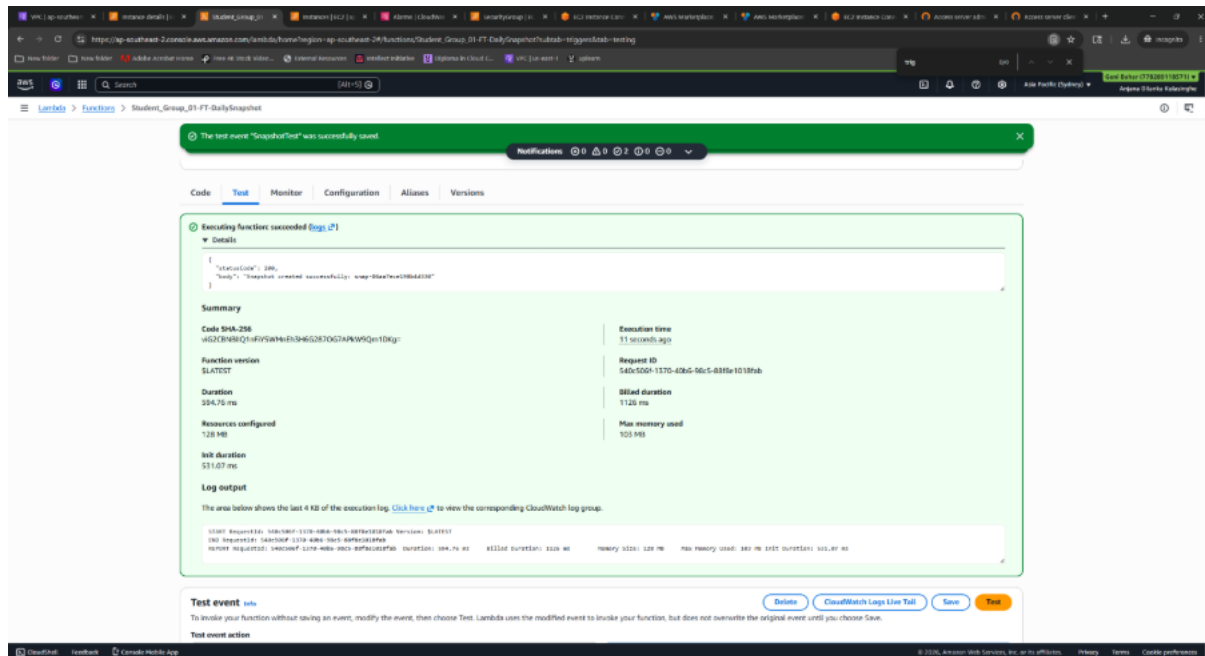

Lambda Function

The Lambda function was developed to automate snapshot creation for selected EBS volumes. Automation reduces administrative effort and improves backup consistency.

Lambda Function Test

The function was executed successfully and returned to a successful completion status, confirming that the automation workflow is operating correctly.

Snapshot Verification

The newly created snapshot appears within the AWS console, confirming that the Lambda function successfully completed the backup operation.

Event Bridge Schedule

Amazon Event Bridge was configured to trigger the Lambda function automatically on a daily schedule. This ensures backups occur consistently without manual intervention.

The image displays two screenshots of the Amazon EventBridge console, showing the configuration of a scheduled rule named "Student_Group_01-FT-DailySnapshotRule".

Screenshot 1: Schedule Detail View

- Schedule detail:**
 - Schedule name: Student_Group_01-FT-DailySnapshotRule
 - Description: -
 - Schedule group name: default
- Status:** Enabled
- Schedule ARN:** arn:aws:scheduler:ap-southeast-2:778289118271:schedule/default/Student_Group_01-FT-DailySnapshotRule
- Action after completion:** NONE
- Schedule start time:** -
- Schedule end time:** -
- Execution time zone:** Pacific/Honolulu
- Flexible time window:** 1 hour
- Created date:** May 28, 2025, 17:36:34 (UTC+12:00)
- Last modified date:** May 28, 2025, 17:36:34 (UTC+12:00)

Schedule: rate(1 days)

Target View:

- Target:** Student_Group_01-FT-DailySnapshot
- Target ARN:** arn:aws:lambda:ap-southeast-2:778289118271:function:Student_Group_01-FT-DailySnapshot
- Service:** AWS Lambda
- API:** Invoke
- Execution role:** Amazon_EventBridge_Scheduler_jAPMDA_v5063ad444

Resource Tagging

Resource tagging was implemented throughout the AWS environment to improve resource identification, management, cost tracking, and governance.

A consistent tagging strategy was used across AWS resources, following the project naming convention required by the assessment. Tags were applied to key infrastructure components including the VPC, subnets, EC2 instances, Security Groups, Load Balancer, database resources, and supporting services.

Tagging enables easier administration, simplifies reporting, and supports future operational management activities within the cloud environment.

The tagging strategy also supports future cost allocation, operational reporting, and resource lifecycle management.

All major AWS resources were tagged using the assessment naming requirement: **Key = Student_Group_01-FT** and **Value = resource identity**. This supports resource tracking, cost visibility, and assessment verification.

The screenshot displays the AWS Management Console interface for a VPC. The left sidebar shows the navigation menu with categories like Virtual private cloud, Security, PrivateLink and Lattice, and Network Firewall. The main content area shows the details for VPC ID vpc-0c6ad58776f0337bc. Key information includes:

- Details:** VPC ID, DNS resolution (enabled), Main network ACL, IPv4 CIDR (10.0.0.0/24), and Enigment control ID.
- Status:** Available.
- Block Public Access:** Off.
- DNS Resolvers:** CloudResolver.
- Tags:** A table showing a single tag with Key 'Student_Group' and Value 'ST-47'.

The screenshot displays the AWS Management Console interface for an Amazon RDS database instance. The left sidebar shows the navigation menu with categories like Aurora and RDS, Databases, and Events. The main content area shows the details for database-1. Key information includes:

- Summary:** DB identifier (database-1), Status (Available), Engine (MySQL Community), and Region (us-east-2).
- Tags:** A table showing a single tag with Key 'Student_Group' and Value 'ST-47'.

WordPress Application Deployment

WordPress was deployed on the AWS application layer to demonstrate a realistic migration target for Yoobee College's web-based infrastructure. The application connects to the RDS database back end and is accessed through the load-balanced HTTPS endpoint. This validates the core functional requirement of hosting a web application in the cloud.

Web Application Setup

A WordPress application was deployed on an Amazon EC2 instance and integrated with Amazon RDS MySQL for database services.

The application architecture separates the web and database tiers to improve security and scalability. WordPress configuration was completed successfully and connectivity between the web server and database server was validated.

WordPress Installation

Apache, PHP, and WordPress components were installed on the EC2 instance. The web server was configured to host the WordPress application and communicate with the backend database service.

Configure WordPress

WordPress was configured to use the Amazon RDS database instance. Application setup was completed successfully, and the website became accessible through the configured Load Balancer and domain name.

```

// wp-config.php
/*
 * The base configuration for WordPress
 *
 * The wp-config.php creation script uses this file during the installation.
 * You don't have to use the website, you can copy this file to "wp-config.php"
 * and fill in the values.
 *
 * This file contains the following configurations:
 *
 * + Database settings
 * + Secret keys
 * + Database table prefix
 * + AUTH_KEY
 *
 * @link https://developer.wordpress.org/advanced-administration/wordpress/wp-config/
 */
// Database settings - You can get this info from your web host //
// The name of the database for WordPress //
define( 'DB_NAME', 'wordpress' );

// Database username //
define( 'DB_USER', 'admin' );

// Database password //
define( 'DB_PASSWORD', 'password' );

// Database hostname //
define( 'DB_HOST', 'database-1.cpqyabsh09.ap-southeast-2.rds.amazonaws.com' );

// Database charset to use in creating database tables //
define( 'DB_CHARSET', 'utf8mb4' );

// The database collate type. Don't change this if in doubt. //
define( 'DB_COLLATE', '' );

/* Authentication unique keys and salts.
 *
 * Change these to different unique phrases! You can generate these using
 * the {@link https://api.wordpress.org/secret-key/1.1/salt/ WordPress.org secret-key service}.
 * You can change these at any point in time to invalidate all existing cookies.
 * This will force all users to have to log in again.
 *
 * @since 2.6.0
 */
define( 'AUTH_KEY',         'put your unique phrase here' );

Verify the website with the Load Balancer DNS

The WordPress website was tested using the Application Load Balancer DNS name to confirm that external traffic was correctly routed to the web server. The successful page load verifies that the ALB listener, target group, health checks, and EC2 web server configuration were functioning correctly.

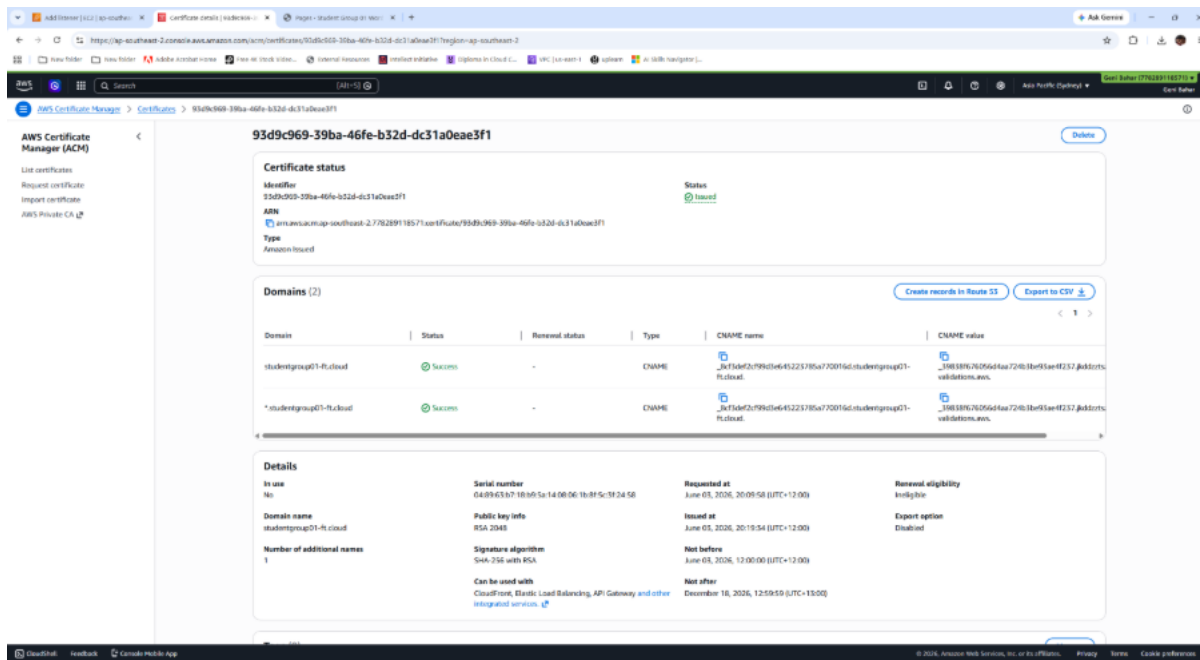

HTTPS Implementation

HTTPS was implemented using AWS Certificate Manager and the Load Balancer listener configuration. This protects data in transit between users and the WordPress application. HTTP access should be redirected to HTTPS where possible to avoid unencrypted traffic.

ACM Certificate Creation

An SSL/TLS certificate was issued through AWS Certificate Manager and attached to the Application Load Balancer. This enables encrypted HTTPS communication between users and the hosted application.

Apply Certificate to LoadBalancer

The ACM SSL/TLS certificate was attached to the HTTPS listener on the Application Load Balancer. This allows the Load Balancer to terminate HTTPS traffic securely and forward requests to the WordPress application, ensuring encrypted communication for users accessing the website.

HTTPS Check

The website was successfully accessed using HTTPS through the public domain name. The SSL/TLS certificate was issued through AWS Certificate Manager and attached to the Application Load Balancer, ensuring encrypted communication between users and the hosted application.

VPN Connection for Azure FortiGate Firewall

FortiGate was included as the dedicated security control point for inter-cloud traffic. The purpose of this component is to inspect, restrict, and manage traffic between AWS and Azure, while supporting secure VPN/routing configuration. FortiGate firewall policies are used to define which traffic is allowed between environments and to reduce the risk of uncontrolled cross-cloud communication.

FortiGate control	Purpose
VPN/routing configuration	Enables controlled connectivity between AWS and Azure components
Firewall policies	Allows only approved inter-cloud traffic
Security inspection	Supports visibility and filtering of traffic flows
Logging	Provides evidence for troubleshooting and incident analysis
Segmentation	Reduces the risk of one cloud environment exposing another

Customer Gateway Creation

An AWS Customer Gateway was created to represent the external FortiGate firewall device located within the Azure environment. The Customer Gateway stores the public IP address of the remote firewall and acts as the AWS endpoint definition for establishing VPN connectivity.

Virtual Private Gateway Creation

A Virtual Private Gateway (VGW) was created and attached to the AWS VPC to provide VPN capabilities for the environment. The VGW acts as the AWS-side VPN endpoint and enables encrypted communication between the VPC and remote networks.

Site-to-Site VPN Connection Creation

A Site-to-Site VPN connection was configured to establish secure communication between AWS and the external FortiGate environment.

The VPN connection uses IPsec encryption and provides secure transport for traffic exchanged between the AWS VPC and remote networks.

VPN Tunnel Configuration

AWS automatically generated two IPsec tunnels to provide redundancy and high availability for the Site-to-Site VPN connection.

The tunnel endpoints were successfully provisioned and made available for integration with the external FortiGate firewall environment. Since the remote FortiGate device had not yet been connected, both tunnels remained in a waiting state.

The screenshot confirms that two VPN tunnels were created successfully. The tunnel provisioning status shows "Available", indicating that the AWS VPN infrastructure was successfully deployed and ready for connection by the external firewall device.

The screenshot displays the AWS VPN console interface. The left-hand navigation pane shows the 'VPN connections' section under 'Virtual private network (VPN)'. The main content area shows a table of VPN connections with the following data:

Name	VPN ID	State	Virtual private gateway	Transit gateway	VPN Concentrator ID	Customer gateway	Customer gateway address	Inside IP version	Type	Category	VPC
AWS-to-Azure-PortGate-VPN	vgn-00c3b54a1a39f1b94	Available	vgn-00c3b54a1a39f1b94	-	-	vgn-00c3b54a1a39f1b94	20.11.94.11	IPv4	IPsec.1	VPN	vpc-0d4e0027b8f81

Below the table, the 'Tunnel state' section for the selected connection shows two tunnels:

Tunnel number	Outside IP address	Inside IPsec CIDR	Inside IPsec CIDR	Status	Provisioning status	Last status change	Details	Certificate ARN
Tunnel 1	3.104.187.23	108.22.471.16/30	-	Down	Available	June 7, 2026, 10:05:39 (UTC-12:00)	-	-
Tunnel 2	52.236.35.163	108.234.109.44/30	-	Down	Available	June 7, 2026, 14:47:51 (UTC-12:00)	-	-

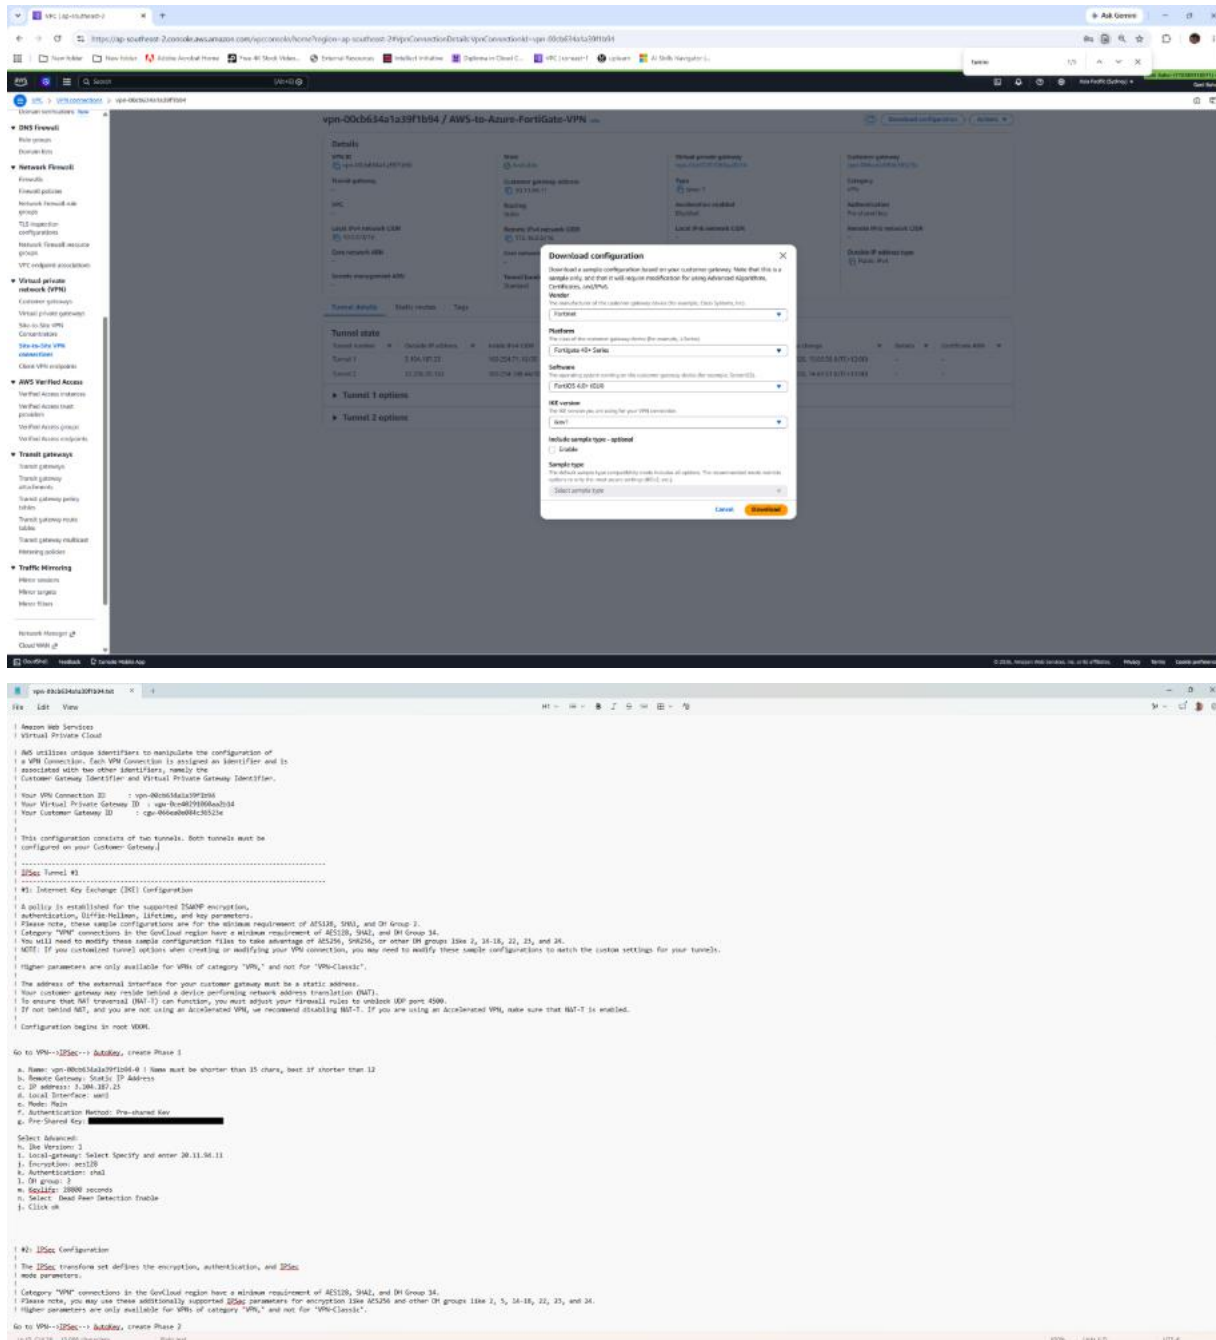

Links for 'Tunnel 1 options' and 'Tunnel 2 options' are provided for each tunnel.

VPN Configuration File Generation

AWS provides vendor-specific VPN configuration files to simplify integration with external firewall devices. A Fortinet FortiGate configuration package was downloaded from the Site-to-Site VPN connection to support future integration with the Azure FortiGate firewall environment.

The generated configuration file contains the tunnel endpoints, Phase 1 and Phase 2 parameters, and authentication settings required to establish secure IPsec connectivity.

The downloaded configuration file provides all parameters required for configuring the remote FortiGate device and simplifies the deployment of the Site-to-Site VPN connection.

The screenshot shows the AWS VPN console interface. On the left, there is a navigation menu with categories like DNS Firewall, Network Firewall, Virtual Private Network (VPN), AWS Verified Access, Transit Gateways, and Traffic Mirroring. The main panel displays the configuration for a specific VPN connection, titled 'vpn-00c6b34a1a39f1b64 / AWS-to-Azure-FortiGate-VPN'. A 'Download configuration' dialog box is open, allowing the user to download the configuration file. The dialog includes fields for 'Vendor' (Fortinet), 'Format' (Fortinet CLI), and 'Tunnel type' (Phase 1 and Phase 2). Below the dialog, the configuration file content is shown, detailing the FortiGate configuration for the VPN connection, including tunnel endpoints, Phase 1 and Phase 2 parameters, and authentication settings.

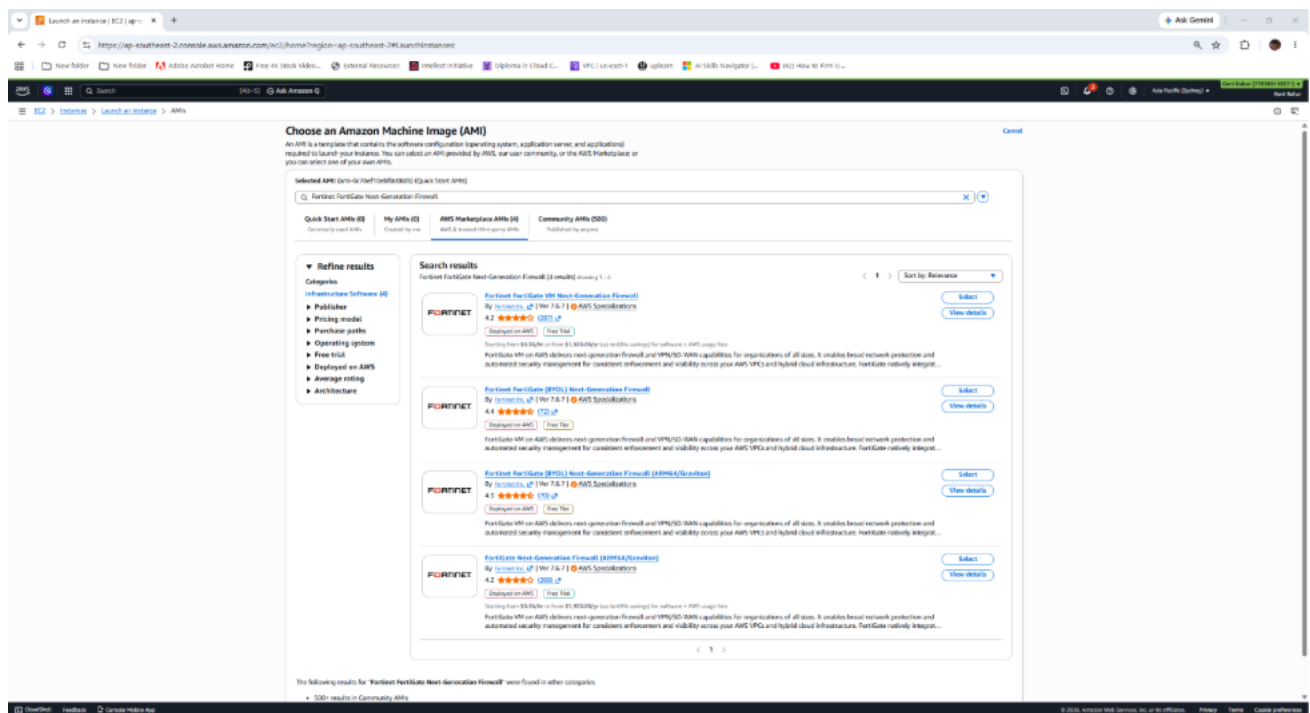

FortiGate Firewall Implementation

FortiGate Next-Generation Firewall was deployed in the AWS environment to demonstrate firewall-based security control for the multi-cloud architecture. The FortiGate instance was configured with public and internal network interfaces to support traffic inspection, routing, and VPN tunnel configuration.

This implementation provides evidence of Fortinet security integration by demonstrating interface configuration, address objects, firewall policies, static routing, and IPsec VPN tunnel preparation.

FortiGate EC2 Instance Deployment

A FortiGate VM instance was deployed in AWS using the Fortinet marketplace image. The instance was placed inside the project VPC and assigned a public IP address to allow administrative access to the FortiGate management console.

Next Steps

What would you like to do next with this instance, for example "create alarm" or "create budget"?

Create billing usage alerts
To manage costs and avoid surprise bills, set up email notifications for billing usage thresholds.
[Create billing alerts](#)

Connect to your instance
Once your instance is running, log into it from your local computer.
[Connect to instance](#)
[Learn more](#)

Connect an RDS database
Configure the connection between an EC2 instance and a database to allow traffic flow between them.
[Connect an RDS database](#)
[Create a new RDS database](#)
[Learn more](#)

Create EBS snapshot policy
Create a policy that automates the creation, retention, and deletion of EBS snapshots.
[Create EBS snapshot policy](#)

Manage detailed monitoring
Enable or disable detailed monitoring for the instance. If you enable detailed monitoring, the Amazon EC2 console displays monitoring graphs with a 1-minute period.
[Manage detailed monitoring](#)

Create Load Balancer
Create a application, network gateway or classic Elastic Load Balancer.
[Create Load Balancer](#)

Create AWS budget
AWS Budgets allows you to create budgets, forecast spend, and take action on your costs and usage from a single location.
[Create AWS budget](#)

Manage CloudWatch alarms
Create or update Amazon CloudWatch alarms for the instance.
[Manage CloudWatch alarms](#)

Disaster recovery for your instances
Recover the instances you just launched into a different Availability Zone or a different Region using AWS Cloud Disaster Recovery (CDR).
[Disaster recovery for your instances](#)

Monitor for suspicious runtime activities
Amazon GuardDuty enables you to continuously monitor for malicious runtime activity and unauthorized behavior, with near real-time visibility into on-host activities occurring across your Amazon EC2 workloads.
[Monitor for suspicious runtime activities](#)

Get instance screenshot
Capture a screenshot from the instance and view it as an image. This is useful for troubleshooting an unreachable instance.
[Get instance screenshot](#)

Get system log
View the instance's system log to troubleshoot issues.
[Get system log](#)

[View all instances](#)

The screenshot shows the AWS Management Console interface for EC2 instances. The left sidebar contains navigation links for Dashboard, IAM, CloudWatch, and other services. The main content area displays a table of instances. The instance 'i-0969751affcc0124' is selected, and its details are shown on the right. The details include the instance's name, ID, public and private IP addresses, instance type, VPC, subnet, and security groups. The instance is currently in the 'Running' state.

This screenshot shows a modal dialog box titled 'Change Source / destination check' overlaid on the AWS console. The dialog contains a message asking for confirmation to change the source or destination check for the selected instance. It includes a 'Change Source / destination check' button and a 'Cancel' button. The background shows the same instance details page as the previous screenshot.

The first screenshot displays the 'Networking' tab for the EC2 instance 'i-096757a5ffad124 (Student_Group_01-FT-FortiGate)'. It shows the VPC ID as 'vpc-0c6d8779b0517be', the subnet ID as 'subnet-0a1e1186', and the public IP address as '100.1.123'. The instance is running in the 'ap-southeast-2' region.

The second screenshot displays the 'Security' tab for the same EC2 instance. It shows the 'Owner ID' as '776380118071' and the 'Launch time' as 'Wed Jan 17 2024 12:44:30 GMT+1200 (New Zealand Standard Time)'. The 'Inbound rules' table lists the following rules:

Name	Security group rule ID	Port range	Protocol	Source	Security groups	Description
sg-0170f453a0b7914	sg-0170f453a0b7914	22	TCP	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	
sg-0c6f7b10e0f61e4	sg-0c6f7b10e0f61e4	4000	UDP	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	
sg-0a55f638f9e10f8	sg-0a55f638f9e10f8	443	TCP	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	
sg-0a68741102d915f8	sg-0a68741102d915f8	400	ICMP	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	
sg-047014102d915f8	sg-047014102d915f8	500	UDP	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	
sg-099079027a0d0c3	sg-099079027a0d0c3	80	TCP	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	

The 'Outbound rules' table lists the following rule:

Name	Security group rule ID	Port range	Protocol	Destination	Security groups	Description
sg-0a6f3c3f2c1c1c4	sg-0a6f3c3f2c1c1c4	All	All	0.0.0.0/0	Student_Group_01-FT-FortiGate-05	

The screenshot displays the AWS Management Console interface for an EC2 instance. The top navigation bar shows the 'Instances' page with a search bar and filters. The left sidebar contains a navigation menu with categories like 'Instances', 'Images', 'Elastic Block Store', 'Network & Security', 'Load Balancing', and 'Auto Scaling'. The main content area shows the details for the instance 'Student_Group_01-FortGate' (Instance ID: i-0965751effad124).

Instance summary:

- Instance ID:** i-0965751effad124

- RAM disk ID:** --

FortiGate Network Interfaces

The FortiGate firewall was configured with two physical interfaces. Port1 was used as the public-facing interface, while Port2 was configured as the internal interface for private network communication. This separation allows FortiGate to inspect and control traffic between external and internal networks.

Name	Type	Members	IP/Netmask	Administrative access	DHCP clients	DHCP ranges	Ref
802.3ad Aggregate	802.3ad Aggregate			PING		10.255.1.2-10.255.1.254	2
FortiLink	FortiLink		Dedicated to FortiSwitch	Security Fabric Connection			
port1	Physical Interface		10.0.1.139/255.255.255.0	PING HTTPS SSH HTTP			0
port2	Physical Interface		0.0.0.0/0.0.0.0	PING HTTPS SSH HTTP			1
NAT interface	Tunnel Interface		0.0.0.0/0.0.0.0				0
WiFi SSID	WiFi SSID		0.0.0.0/0.0.0.0				0

FortiGate Address Objects

Address objects were created to represent important AWS and Azure network ranges. These objects simplify firewall policy configuration and make the rules easier to manage and understand.

Name	Type	Interface	Details	IP	Ref
AWS VPC	Subnet			10.0.0.0/16	0
AWS VPC-Server	Subnet			100.0.0.0/24	0
Azure VNet	Subnet			10.0.0.0/16	0
FABRIC_DEVICE	Subnet			0.0.0.0/0	0
FIREWALL_AUTH_PORTAL_ADDRESS	Subnet			0.0.0.0/0	0
SSI VPN_TUNNEL_ADDR1	IP Range			10.212.134.200-10.212.134.210	0
all	Subnet			0.0.0.0/0	1
gmail.com	FQDN		gmail.com		1
login.microsoft.com	FQDN		login.microsoft.com		1
login.microsoftonline.com	FQDN		login.microsoftonline.com		1
login.windows.net	FQDN		login.windows.net		1
metadata-server	Subnet			169.254.169.254/32	0
none	Subnet			0.0.0.0/0	0
port2 address	Interface Subnet	port2		0.0.0.0/32	0
wildcard.dropbox.com	FQDN		*.dropbox.com		0
wildcard.google.com	FQDN		*.google.com		1

FortiGate Firewall Policies

Firewall policies were created to control traffic between the AWS environment and the planned Azure network. The policies define allowed communication paths and demonstrate how FortiGate can enforce traffic control between cloud environments.

FortiGate Static Routes

Static routes were configured to define traffic paths between the AWS network and the planned Azure network. These routes support future multi-cloud connectivity and ensure traffic is directed through the correct FortiGate interfaces.

FortiGate IPsec VPN Tunnel Configuration

IPsec VPN tunnel settings were configured using the AWS-generated Fortinet VPN configuration file. The Phase 1 and Phase 2 parameters include IKE version, encryption, authentication, Diffie-Hellman group, key lifetime, and PFS settings.

The VPN tunnel remained inactive during testing because the remote Azure-side endpoint was not fully deployed. However, the FortiGate-side VPN configuration was prepared and ready for integration.

Verify Tunnel with Azure

FortiGate Events

FortiGate system event logs were reviewed to verify administrative activity and configuration changes. Forward traffic logs were not populated because production traffic was not routed through the FortiGate firewall during this proof-of-concept stage.

The screenshot shows the FortiGate FortiView Log View page. The left sidebar contains navigation options: Dashboard, Status, Security, Network, and various FortiView views. The main content area displays a table of traffic logs:

Date/Time	Source	Device	Destination	Application Name	Sent / Received
2026/06/16 19:29:34	10.0.1.139		173.243.141.16 (logjo.fortinet.net)	HTTPS	635 kB / 10.24 kB
2026/06/16 19:27:08	10.0.1.139		208.91.112.60 (ntp2.fortiguard.com)	NTP	76 B / 76 B
2026/06/16 19:27:08	10.0.1.139		208.91.112.61 (ntp3.fortiguard.com)	NTP	76 B / 76 B
2026/06/16 19:27:08	10.0.1.139		208.91.112.62 (ntp2.fortiguard.com)	NTP	76 B / 76 B
2026/06/16 19:27:08	10.0.1.139		208.91.112.63 (ntp1.fortiguard.com)	NTP	76 B / 76 B

AWS Implementation Conclusion

The AWS implementation successfully demonstrates a secure, scalable, and monitored hosting platform for the WordPress migration scenario. The design uses a custom VPC, public/private subnet separation, Security Groups, IAM roles, RDS, S3, Lambda, CloudWatch, SNS, ELB, Auto Scaling, ACM, and OpenVPN to address the project requirements. Security was considered through least-privilege access, restricted network paths, encryption, HTTPS, monitoring, and backup automation. The AWS environment also supports integration with Azure DNS and Fortinet FortiGate, allowing the project to meet the broader multi-cloud security integration objective.

Task 2: Part B | Project Implementation using Azure Cloud Services (Yusof)

This section documents the Microsoft Azure implementation used to support the multi-cloud security project. Azure was used for subscription governance, account security, RBAC, MFA, Azure AD tenant configuration, Azure DNS, and external testing of secure access to the AWS-hosted WordPress application. The purpose of this section is to show how Azure services were integrated with AWS-hosted infrastructure to provide identity, access control, DNS name resolution, and secure connectivity validation.

Azure Subscriptions - Configuration.

The first action We performed to implement Azure was to create an individual (dedicated) subscription. The reason for this is to provide a single place to manage our expenses and where all of our cloud resources will be contained; and therefore, can be managed as a singular entity. We set up a Pay-As-You-Go account for the subscription. We went back into the billing account section of the Azure Portal and created a new subscription using that method. Before completing the creation of the new subscription, we confirmed that our billing information was correctly populated within the billing profile/sections area. After completion of the new subscription creation, we then transferred the ownership of that new subscription over to the newly created Azure Active Directory Tenant. Transferring the ownership from our personal directory to the project specific directory enabled me to deploy all subsequent resources to the correct logical grouping. As such, once We had transferred the ownership of the subscription, we could ensure that all future deployments would remain associated with our Project-specific Directory versus being associated with our Default Personal Directory.

Owner	Grants full access to manage all r...	This resource	--	Add
User Access Administrator	Lets you manage user access to ...	Root (inherited)	--	None

Implementing role-based access control and multi-factor authentication

To secure the Azure environment was a major concern for me, we chose to implement both Role-Based Access Control and multi-factor authentication from the beginning. In doing so, we turned on security defaults in Microsoft Entra Id, which forced all users to register for MFA (multi-factor authentication), and disabled legacy authentication protocols. The result was an immediate reduction in risk of being attacked with a reduced attack surface, since none would be able to access the tenant until the completion of another two-step form of verification.

With regards to access controls, we evaluated each of the roles assigned to our team members at both the subscription and resource group levels. As it pertained to ourself, we maintained ownership over our account to allow me to have full administrative authority to provision and configure core infrastructure. However, the remaining team members, whom required the ability to make deployments and manage resources, were given the contributor role at the resource group level. The contributor role allowed them to create and edit resources such as virtual networks and dns zone(s), however, did not grant them permission to add or remove contributors or view billable items. By implementing permissions in this manner, we granted each member what they required, while maintaining the principle of least privilege through-out the course of the project.

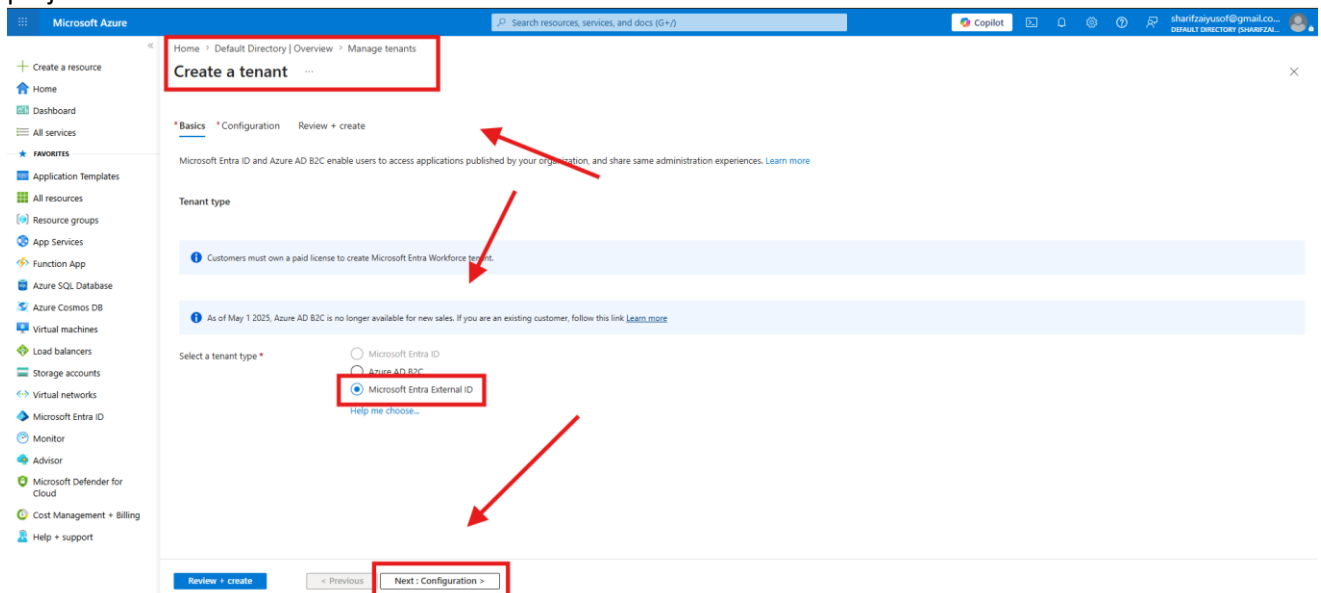

Control	Purpose
RBAC	Limits user permissions based on assigned role
MFA	Adds extra authentication protection
Azure AD tenant	Provides identity and access management boundary
Subscription access control	Ensures only approved users can manage resources

Creating an Azure Active Directory Tenant for the Project

The next step in creating a defined boundary of identities for the project involved the creation of a new Microsoft Entra ID tenant called "Student_Group_01_FT". In creating the tenant, we provided an organization name; established the first domain to be studentgroup01ft.onmicrosoft.com; chose "Australia" from the list of countries/regions; associated this tenant to the active Azure subscription to which We have access; and added it to a resource group that is common to both this new tenant and existing project related resources. Upon completion of the provisioning process, the newly created tenant was visible in addition to our original directory in the AAD management portal. We then switched subscriptions to allow any additional Azure resources to be assigned to this tenant as well as ensure that they are managed under this tenant's organizational identity. The advantages of separating our resources included better auditing capabilities and improved administrative control over who can access what based on their roles in the project.

DNS Integration with AWS (Azure DNS Zone and Registrar Update)

DNS integration with hosted WordPress on AWS through an update of our Azure DNS Zone and Registrar. To connect our hosted WordPress on AWS to the Azure DNS services, we had to configure the two separately. We first bought a DNS from **porkbun.com** named studentgroup01-ft.cloud and then configured our Azure DNS Services by creating a Public DNS Zone for studentgroup01-ft.cloud. The four Authoritative Name Servers were automatically generated for me when We created the zone. Then, we went back to our Domain Registrar and replaced their Default Name Servers with the newly created Azure Name Servers. The process delegated all future DNS Record Management to be done from within the Azure Portal.

Once the Zone was activated, we set up all of the DNS Records needed for public access. We created a CNAME record at the level of the www sub-domain that pointed it to the AWS Application Load Balancer that was serving WordPress Site created by team member **Geni**. With this single alias, we was able to provide visitors to our website with a clean-branded domain name vs. one of the long URLs that AWS generates. We also established the required DNS Validation Record for **Geni** so they could verify our ownership of the domain and thus generate a legitimate SSL/TLS certificate for the site. Once the DNS Propagation was completed, we verified that our domain was resolved as expected.

Testing Through VPN Client Services

Once the complete Azure setup was done, we wanted to confirm that the hybrid connection from Azure to AWS was actually operational. The initial setup included the creation of the Virtual Network (VNet) with 2 subnets. One subnet was named s-net-workload and the second one was the required GatewaySubnet; this was reserved for the VPN gateway.

The VPN gateway itself was using the VpnGw1AZ SKU which provided zone redundant high availability. The gateway type was VPN with Route-Based Routing; this supported the IPsec config on the FortiGate appliance at AWS. A Public IP Address (4.237.252.129) was assigned to the gateway to allow it to connect to the FortiGate.

For AWS We created a Local Network Gateway (Ing-aws-FortiGate) which represented the FortiGate device within Azure. The public IP address of the FortiGate (16.176.93.13) and the AWS VPC address space (10.0.0.0 /16) were added to provide to Azure what networks were available through the tunnel.

Upon configuring each end of the VPN tunnel, we created the site-to-site VPN connection "conn-Azure-to-aws-FortiGate". The Connection Type was IPsec which is the typical method of encrypting VPN tunnel traffic. Upon checking the status, it indicated that it was connected; therefore, the tunnel had been established and was transmitting data.

In order to test that there was full communication throughout the entire path, Geni tried pinging the private IP of the EC2 that had WordPress installed via the VPN tunnel. The ping worked which allowed me to determine that the routing had been established correctly along with both Security Groups and Network Security Groups allowing traffic to flow between them. In addition, we verified that access to WordPress was still possible via its public Domain Name using HTTPS without any issues. This allowed me to confirm that the Hybrid Network Path had been validated and functioning properly.

Final Outcome: Secure HTTPS Access Through Azure DNS

Ultimately, the purpose behind implementing the multi-cloud solution was for the student group's WordPress site to be available over the internet from anywhere in the world using an HTTPS connection. After waiting for the dns records to propagate through the Internet and after validation of the SSL/TLS certificate; We checked the site out by just entering the site's domain into a web browser.

the site worked properly when viewed at [HTTPS://www.studentgroup01-ft.cloud](https://www.studentgroup01-ft.cloud). In addition, there is a padlock icon shown on the left side of the URL bar indicating that the SSL/TLS certificate is being recognized and used as expected. There are no error messages showing within the WordPress

content either. Therefore, it shows that Azure DNS was successfully resolving the domain to AWS Application Load Balancer and that the multi-cloud configuration was successful.

As planned; everything was functioning as expected. With the multi-cloud configuration, Azure will continue to manage identities and global dns resolutions and aws will continue to manage hosting of the student group's WordPress site. To users; accessing the site is transparent with a clean domain name.

The final test confirms that the WordPress website was reachable using the DNS name configured through Azure DNS and that secure HTTPS access was available. This validates the core multi-cloud requirement: Azure provides DNS integration while AWS hosts the application workload behind secure infrastructure.

Task 2: Part-C | Multi-Cloud Security Integration using AWS, Azure and Fortinet (Geni)

This section explains how the three main parts of the project connect together. In our setup, AWS hosts the WordPress workload, Azure is used for DNS, identity and access validation, and FortiGate is used as the security-focused component for firewall control and VPN/routing.

Area	What we configured	Why it mattered
AWS hosting	WordPress hosted using EC2, RDS, ELB, Auto Scaling, ACM, S3, Lambda, CloudWatch, SNS, and IAM	Provides scalable and monitored application hosting
Azure identity and governance	Azure RBAC, MFA, Azure AD tenant, subscription validation	Improves account security and controlled administration
Azure DNS integration	Azure DNS resolves the website name to the AWS load balancer endpoint	Demonstrates multi-cloud service integration
Fortinet FortiGate	Firewall/VPN/security control point between AWS and Azure	Controls and inspects inter-cloud traffic
Secure remote access	OpenVPN/VPN client testing	Reduces direct exposure of private resources
Monitoring and logs	CloudWatch, CloudTrail, Azure monitoring, FortiGate logs where available	Supports detection, troubleshooting, and incident response
Encryption	HTTPS/ACM and AWS encryption services	Protects data in transit and supports data-at-rest protection

The evidence for this integration is not shown in one single console screen because each product has its own portal. AWS evidence is shown in Task 2 Part A, Azure evidence is shown in Task 2 Part B, and FortiGate evidence is shown in the VPN/FortiGate section. Together, these screenshots show how the final multi-cloud setup was built.

The main security idea in this project was to avoid giving open access everywhere. AWS Security Groups, route tables, NACL review, VPN access and FortiGate rules were used to control network access. IAM roles were used in AWS, while RBAC and MFA were used in Azure. Monitoring was also included so issues can be found and investigated.

Further details are shown in the screenshots above. This section is kept short because the actual configuration evidence is already included in the AWS, Azure and FortiGate parts of the report. One limitation we noticed is that multi-cloud work is not always easy to prove in one screenshot. The evidence is spread across AWS, Azure and FortiGate, but together it shows how each part contributed to the final design.

Requirement Area	Evidence Location
AWS workload hosting	Task 2 Part A: VPC, EC2, RDS, S3, Lambda, ELB, Auto Scaling, ACM
Azure integration	Task 2 Part B: Azure subscription, RBAC/MFA, Azure AD, Azure DNS
Fortinet security	Task 2 Part A FortiGate/VPN section and Task 2 Part C
Monitoring and logging	CloudWatch, CloudTrail, SNS, Azure Monitor and FortiGate log references

Backup and recovery	S3 backup, Lambda snapshot automation, RDS snapshots
Incident handling	Task 3 Part B: EC2 Security Group misconfiguration

Task 3: Risk Assessment and Security Incident Analysis

Task 3: Part A | Risk Assessment and Mitigation Strategy (Geni)

In this section, I identified the main risks we noticed in the multi-cloud design. The risks cover AWS hosting, Azure DNS and identity, FortiGate controls, VPN connectivity, monitoring and backup. The aim of this risk assessment is to show what can go wrong and how we can reduce the impact. I used Low, Medium and High ratings for likelihood and impact, and the mitigation steps are based on what we implemented or reviewed in the project.

Risk ID	Risk Area	Description of Risk	Likelihood	Impact	Mitigation Strategy
R1	AWS IAM	IAM roles or policies may be over-permissive, allowing users or services to access resources beyond their required responsibilities.	Medium	High	Apply least-privilege IAM policies, avoid shared credentials, use IAM roles instead of access keys, enable MFA for administrator access, and review permissions before final submission.
R2	AWS Security Groups	A Security Group may be misconfigured to allow SSH, database, or management ports from 0.0.0.0/0, exposing resources to the internet.	Medium	High	Restrict SSH/admin access to VPN subnet or approved administrator IPs only, review inbound rules, remove unused ports, and monitor changes using CloudTrail and CloudWatch.
R3	AWS RDS Database	The RDS database may be publicly accessible or allow MySQL access from unapproved sources.	Low	High	Place RDS in private subnet, disable public accessibility, allow MySQL only from the application Security Group, enable encryption, and take regular snapshots.
R4	Data Protection	Backup data or database storage may be exposed if encryption or access control is not configured correctly.	Medium	High	Enable S3 server-side encryption, RDS encryption, restrict S3 bucket public access, use IAM-controlled access, and validate backup permissions.
R5	Azure Identity and RBAC	Azure users may be given excessive permissions or MFA may not be enforced,	Medium	High	Enable MFA, assign RBAC roles based on job responsibility, avoid owner-level access unless

		increasing the risk of account compromise.			required, and review access assignments.
R6	Azure DNS	Incorrect Azure DNS records may point users to the wrong endpoint or make the WordPress site unavailable.	Medium	Medium	Validate DNS records, check name server configuration, test HTTPS access from an external client, and document final DNS configuration.
R7	Fortinet FortiGate Policy	Firewall policies may be too open or incorrectly ordered, allowing unapproved traffic between AWS and Azure.	Medium	High	Apply deny-by-default approach, allow only required traffic, document firewall rules, enable FortiGate logging, and test allowed/blocked traffic paths.
R8	VPN Exposure	VPN or OpenVPN access may be exposed to unauthorised users or weak authentication, allowing attackers to target private resources.	Medium	High	Restrict VPN access to approved users, use strong authentication, limit VPN Security Group rules, monitor VPN login attempts, and remove unused accounts.
R9	Monitoring Gaps	Security events may not be detected if CloudWatch, CloudTrail, Azure Monitor, or FortiGate logs are not enabled or reviewed.	Medium	High	Enable CloudWatch alarms, CloudTrail audit logging, Azure Monitor checks, FortiGate logs, and SNS notifications for important events.
R10	Backup and Recovery Failure	Lambda snapshot automation or S3 backup storage may fail, leaving the environment without a reliable recovery point.	Low	High	Test Lambda snapshot execution, review CloudWatch logs, verify S3 backup storage, and confirm snapshots are created successfully.
R11	Multi-Cloud Dependency	Failure in one cloud component, such as Azure DNS or FortiGate routing, can affect access to AWS-hosted services.	Medium	High	Document dependency paths, test AWS access directly and through Azure DNS, validate FortiGate/VPN paths, and maintain recovery steps for each component.
R12	Human Error / Change Management	Team members may accidentally modify firewall, IAM, DNS, or	Medium	High	Use peer review for configuration changes, record major changes,

		Security Group settings without review.			review screenshots before submission, and apply least privilege to reduce accidental impact.
--	--	---	--	--	--

Shared Risk and Dependency Discussion

Because the project uses AWS, Azure and Fortinet together, some risks are shared. For example, the WordPress site is hosted in AWS, but access also depends on Azure DNS. If the DNS record is wrong, users may not reach the site even if AWS is working correctly. In the same way, FortiGate or VPN routing issues can affect traffic between the cloud environments.

Access control is another shared risk. AWS IAM controls the AWS side, while Azure RBAC and MFA control the Azure side. If either side is too open, the whole design becomes weaker. Monitoring is also split across different tools such as CloudWatch, CloudTrail, Azure Monitor and FortiGate logs, so they need to be checked together.

The mitigation approach is based on having more than one layer of protection. Network access is controlled using Security Groups, NACL review, VPN and FortiGate policies. Identity is controlled using IAM roles, RBAC and MFA. Data protection is handled using encryption and restricted S3/RDS access. Backup and monitoring support recovery if something goes wrong.

Task 3: Part B | Security Incident Analysis (Hari)

Selected Incident: EC2 Security Group Misconfiguration Allowing Public SSH Access

During our implementation and testing stage, we found a security configuration issue in the AWS EC2 environment used for the WordPress deployment. One EC2 Security Group rule allowed SSH access on port 22 from 0.0.0.0/0, meaning the instance could receive SSH connection attempts from any public IP address.

I treated this as a security issue because management access should not be open to the public internet. In the intended design, SSH access should only be available through a controlled path such as VPN, FortiGate access, or a trusted IP address. The EC2 instance still required key-based authentication, but the open SSH rule still increased the attack surface.

We found this issue while reviewing AWS Security Group rules and testing evidence. The response was simple but important: identify the risky rule, correct the inbound access, review related controls, and record the lesson learned.

Incident Detection and Response Timeline

Time	Event / Activity	Evidence / Tool Used	Action Taken
05:30 PM	EC2 Security Group rule was found allowing SSH port 22 from 0.0.0.0/0.	AWS EC2 Security Group inbound rules	The rule was identified as risky because SSH was open to the public internet.
05:45 PM	Team reviewed whether SSH access was required from the internet.	AWS EC2 configuration and project design	Confirmed that public SSH access was not required for the final secure design.
06:00 PM	The Security Group rule was updated.	AWS EC2 Security Group console	Public SSH access was removed or restricted to a trusted access path.
06:15 PM	VPN and FortiGate access design was reviewed.	OpenVPN/FortiGate configuration evidence	Confirmed that administrative access should be handled through a controlled secure path.
06:30 PM	Related access controls were reviewed.	IAM, Security Groups, RDS Security Group, Azure RBAC/MFA	Checked whether similar risky access rules existed in other parts of the project.
06:45 PM	Monitoring and logging sources were reviewed for incident analysis.	CloudTrail, CloudWatch, Azure Monitor, FortiGate logs where available	Identified what evidence would support detection and troubleshooting.
07:00 PM	Findings and improvements were documented.	Project report and screenshots	Added lessons learned and prevention actions to the report.

Roles and Responsibilities

Role	Team Member	Responsibility During the Incident
AWS Implementation Lead	Geni Bahar	Reviewed AWS EC2 Security Group rules, corrected the risky inbound rule, checked IAM and EC2 exposure, and documented the AWS-side response.
Azure Implementation Lead	Yusof Sharifzai	Verified that Azure DNS, Azure AD, RBAC, and MFA were not directly affected by the AWS Security Group issue.
Project Coordinator / Testing Support	Hari Tamang	Supported screenshot collection, project documentation, and verification of testing evidence.
Fortinet / VPN Review	Geni Bahar with group support	Reviewed the intended FortiGate/VPN access path and confirmed that management access should not rely on public SSH exposure.

Detection and Investigation

We detected the issue while manually checking the EC2 Security Group rules. The inbound SSH rule from 0.0.0.0/0 was risky because any public IP address could try to connect to the EC2 instance.

For the investigation, we mainly checked three things:

1. Was public SSH access required for the project?
2. Was the EC2 instance still protected by authentication?
3. Was similar risky access rules present in other services?

We confirmed that public SSH access was not needed for the final design. Access should be restricted to the VPN path, FortiGate-controlled access, or a trusted IP address. The instance still required key-based authentication, so this was mainly an exposure issue rather than confirmed unauthorised access. We also checked related areas such as IAM permissions, RDS Security Group rules, VPN access, Azure RBAC/MFA and FortiGate policy design.

Logging and Monitoring Evidence

The screenshots and configuration evidence in Task 2 support this incident analysis because they show the Security Group, CloudWatch, CloudTrail, VPN/FortiGate, and Azure control areas that were reviewed during testing.

Evidence Source	What Was Checked	Relevance to Incident
AWS EC2 Security Group	Inbound SSH rule and source range	Confirmed that port 22 was open from 0.0.0.0/0.
AWS CloudTrail	Security Group change activity	Useful for identifying when and how Security Group rules were changed.
AWS CloudWatch	EC2 monitoring and alerting capability	Useful for monitoring unusual activity or operational issues.
EC2 System Logs	Server access/authentication logs where available	Useful for checking whether login attempts occurred.
FortiGate Logs / Policies	VPN/firewall access path and traffic control	Useful for confirming that management traffic should be controlled through firewall/VPN rules.

Azure Monitor / Azure AD Review	Azure DNS, identity, and access status	Confirmed that the issue was limited to AWS EC2 access control and did not directly affect Azure identity or DNS.
------------------------------------	---	---

Response Actions

First, the SSH rule was removed or restricted so port 22 was no longer open to 0.0.0.0/0. This immediately reduced the exposure of the EC2 instance.

Second, we confirmed the correct way to access the environment. The VPN and FortiGate design should be used for controlled access rather than direct public SSH.

Third, we reviewed related controls such as IAM roles, EC2 Security Groups, RDS Security Group rules, VPN access, Azure RBAC/MFA and FortiGate policy design to check if the same type of issue existed anywhere else.

Finally, we documented the issue as part of the report because it was a good example of how a small configuration mistake can weaken a cloud design.

Recovery Plan

Immediate Recovery:

The public SSH exposure was corrected by removing or restricting the inbound rule for port 22. SSH access was limited to a trusted access path such as VPN, FortiGate-controlled access, or an approved IP address.

Short-Term Recovery:

All Security Groups were reviewed to identify any other risky inbound rules. IAM permissions were checked to ensure that AWS services used least-privilege access. RDS access rules were reviewed to confirm that the database was not publicly exposed.

Long-Term Recovery:

The team should use a simple change review process before modifying Security Groups, firewall policies, IAM permissions, DNS records, or VPN settings. Security Group rules should be checked again before final submission. Monitoring tools such as CloudTrail, CloudWatch, Azure Monitor, and FortiGate logs should be used where possible to support future troubleshooting and incident analysis.

Lessons Learned

This incident showed me that even a small Security Group mistake can create a serious weakness. Opening SSH to the public internet may happen during testing, but it should not remain in the final setup.

We also learned that cloud security has to be checked at multiple layers. Security Groups control AWS resource access, IAM controls permissions, FortiGate and VPN control secure access paths, and Azure RBAC/MFA protects Azure administration. If one layer is too open, the whole solution becomes weaker.

The main lesson is that access rules should always be reviewed before final submission or production deployment. Management access should only be allowed through trusted and controlled paths.

Conclusion

The issue was handled by correcting the EC2 Security Group rule, restricting SSH access, and reviewing the related AWS, Azure and FortiGate controls. It was a useful project lesson about checking access rules before final submission.

Final Verification Summary

Verification Item	Result
AWS VPC and subnet design	Completed
EC2 WordPress deployment	Completed
RDS database setup	Completed
Load Balancer and Auto Scaling	Completed
S3/Lambda backup design	Completed
CloudWatch/SNS monitoring	Completed
Azure DNS and HTTPS testing	Completed
FortiGate/VPN security integration	Completed
Risk assessment	Completed
Security incident analysis	Completed
